## Journals and Organizations

The latest results from research of least squares applications in geodesy, surveying, mapping, and photogrammetry are published in a variety of journals.

Two international magazines under the auspices of the International Association of Geodesy, both published by Springer-Verlag (Berlin/Heidelberg/New York), are:

*Bulletin Géodésique*

*Manuscripta Geodetica*

Geodesy- and geophysics-related articles can be found in:

American Geophysical Union, Washington, D.C.: *EOS* and *Journal of Geophysical Research*

Royal Astronomical Society, London: *Geophysical Journal International*

Statistical articles related to kinematic GPS can be found in:

Institute of Navigation: *Navigation*

Many national mapping organizations publish journals in which recent statistical applications in geodesy/surveying/mapping/photogrammetry are documented:

American Congress of Surveying and Mapping: *Surveying and Land Information Systems* and *Cartography and Geographic Information Systems*

American Society of Photogrammetry and Remote Sensing: *Photogrammetric Engineering & Remote Sensing*

American Society of Civil Engineers: *Journal of Surveying Engineering*

Deutscher Verein für Vermessungswesen: *Zeitschrift für Vermessungswesen*, Konrad Wittwer  
Verlag, Stuttgart

Canadian Institute of Geomatics: *Geomatica*

Royal Society of Chartered Surveyors: *Survey Review*

Institute of Surveyors of Australia: *Australian Surveyor*

Worth special mention are the following trade magazines:

*GPS World*, published by Advanstar Communications, Eugene, OR

*P.O.B. (Point of Beginning)*, published by P.O.B. Publishing Co., Canton, MI

*Professional Surveyor*, published by American Surveyors Publishing Co., Arlington,  
VA

*Geodetical Info Magazine*, published by Geodetical Information & Trading Centre bv., Lemmer,  
the Netherlands

National mapping organizations such as the U.S. National Geodetic Survey (NGS) regularly  
make software available (free and at cost). Information can be obtained from:

The global positioning system (GPS) has become a tool used in a variety of fields both within and outside engineering.

Positioning has become possible with accuracies ranging from the subcentimeter level—for high-accuracy geodetic applications as used in state, national, and global geodetic networks, deformation analysis in engineering, and geophysics—to the hectometer level in navigation applications. Similar to the space domain, a variety of accuracy classes may be assigned to the time domain: GPS provides position and velocity determinations averaged over time spans from subseconds (instantaneous) to one or two days. Stationary applications of the observatory type are used in GPS tracking for orbit improvement.

---

**149.1 A Satellite Orbiting the Earth**

---

The path of an earth-orbiting satellite is similar to that of a planet around the sun. In history the solution to the motion of planets around the sun was found before its explanation. Johannes Kepler discovered certain regularities in the motions of planets around the sun. Through the analysis of his own observations and those made by Tycho Brahe, he formulated the following three laws:

*First law (1609):*

The orbit of each planet around the sun is an ellipse. The sun is in one of the two focal points.

*Second law* (1609):

The line from sun to planet sweeps out equal areas in equal time periods.

*Third law* (1611):

The ratio between the square of a planet's orbital period and the third power of its average distance from the sun is constant.

Kepler's third law leads to the famous equation

$$n^2 a^3 = GM \quad (149.1)$$

where  $n$  is the average angular rate and  $a$  the semimajor axis of the orbital ellipse.

In 1665-1666 Newton formulated his more fundamental laws of nature (which were only published after 1687) and showed that Kepler's laws follow from them.

## 149.2 The Orbital Ellipse

In a (quasi-)inertial frame the ellipse of an earth-orbiting satellite has to be positioned: the focal point will coincide with the center of mass (CoM) of the earth. Instead of picturing the ellipse itself, we project the ellipse on a celestial sphere centered at the CoM. On the celestial sphere we also project the earth's equator (see Fig. 149.1).

**Figure 149.1** Celestial sphere with projected orbital ellipse and equator.

The orientation of the orbital ellipse requires three orientation angles with respect to the inertial frame XYZ: two for the orientation of the plane of the orbit,  $\Omega$  and  $I$ , and one for the orientation of the ellipse in the orbital plane, for which one refers to the point of closest approach, the perigee,  $\omega$ .

$\Omega$  represents the right ascension ( $\alpha$ ) of the ascending node. The ascending node is the (projected) point where the satellite rises above the equator plane.

$I$  represents the inclination of the orbital plane with respect to the equator

plane.

$\omega$  represents the argument of perigee—the angle from the ascending node (in the plane of the orbit) to the perigee (for planets, the perihelion), which is that point where the satellite (planet) approaches the closest to the earth (sun), or, more precisely, the center of mass of the earth (sun).

Similar to the Earth's ellipsoid, we define the orbital ellipse by a semimajor axis  $a$  and eccentricity  $e$ . In orbital mechanics it is unusual to describe the shape of the orbital ellipse by its flattening.

The position of the satellite in the orbital plane is depicted in Fig. 149.2.

**Figure 149.2** The position of the satellite ( $S$ ) in the orbital plane.

In Fig. 149.2 the major variables are defined as follows:

$a$  = the semimajor axis of the orbital ellipse

$b$  = the semiminor axis of the orbital ellipse

$e$  = the eccentricity of the orbital ellipse, with

$$e^2 = \frac{a^2 - b^2}{a^2} \quad (149.2)$$

$\nu$  = the true anomaly, sometimes denoted by  $f$

$E$  = the eccentric anomaly

The relation between the true anomaly and the eccentric anomaly can be derived

as

$$\tan\left(\frac{E}{2}\right) = \sqrt{\frac{1-e}{1+e}} \cdot \tan\left(\frac{\nu}{2}\right) \quad (149.3)$$

The Cartesian coordinates of the satellite position are

$$X_I = \begin{pmatrix} X \\ Y \\ Z \end{pmatrix} = \mathcal{R}_3(-\omega) \cdot \mathcal{R}_1(-I) \cdot \mathcal{R}_3(-\Omega) \cdot \begin{pmatrix} a \cdot (\cos E - e) \\ a \cdot \sqrt{1-e^2} \cdot \sin E \\ 0 \end{pmatrix} \quad (149.4)$$

In Eq. (149.4) the Cartesian coordinates are expressed in terms of the six so-called Keplerian elements:  $a$ ,  $e$ ,  $I$ ,  $\Omega$ ,  $\omega$ , and  $E$ . If we know the position of the satellite at an epoch  $t_0$  through  $\{a, e, I, \Omega, \omega, E_0\}$ , we are capable of computing the position of the satellite at an arbitrary epoch  $t$  through Eq. (149.4) if we know the relationship in time between  $E$  and  $E_0$ . In other words, how does the angle  $E$  increase with time?

We define an auxiliary variable (angle)  $M$  that increases linearly in time with the mean motion  $n [= (GM/a^3)^{1/2}]$  according to Kepler's third law. The angle  $M$ , the mean anomaly, may be expressed as function of time by

$$M = M_0 + n \cdot (t - t_0) \quad (149.5)$$

Through *Kepler's equation*,

$$M = E - e \cdot \sin E \quad (149.6)$$

the (time) relationship between  $M$  and  $E$  is given. Kepler's equation is the direct result of the enforcement of Kepler's second law ("equal area law").

Combining Eqs. (5) and (6) gives an equation that expresses the relationship between a given eccentric anomaly  $E_0$  (or  $M_0$  or  $\nu_0$ ) at an epoch  $t_0$  and the eccentric anomaly  $E$  at an arbitrary epoch  $t$ :

$$E - E_0 = e \cdot (\sin E - \sin E_0) + n \cdot (t - t_0) \quad (149.7)$$

The transformation is complete when we express the velocity vector  $\{\dot{X}, \dot{Y}, \dot{Z}\}$  in terms of those Keplerian elements. Differentiating Eq. (149.4) with respect to time and combining the position and velocity components into one expression, we get

$$[X_I | \dot{X}_I] = \begin{bmatrix} X | \dot{X} \\ Y | \dot{Y} \\ Z | \dot{Z} \end{bmatrix} \quad (149.8)$$

$$= \mathcal{R}_3(-\omega) \cdot \mathcal{R}_1(-I) \cdot \mathcal{R}_3(-\omega) \begin{bmatrix} a(\cos E - e) & | & -a\dot{E} \sin E \\ a\sqrt{1-e^2} \sin E & | & a\dot{E} \sqrt{1-e^2} \cos E \\ 0 & | & 0 \end{bmatrix} \quad (149.9)$$

The remaining variable  $\dot{E}$  is obtained through differentiation of Eq. (149.6):

$$\dot{E} = \frac{n}{1 - e \cdot \cos E} \quad (149.10)$$

Now all six Cartesian orbital elements (state vector elements) are expressed in terms of the six Keplerian elements.

## 149.3 Relationship between Cartesian and Keplerian Orbital Elements

---

To compute the inertial position of a satellite in a central force field, it is simpler to perform a time update in the Keplerian elements than in the Cartesian elements. The time update takes place through Eqs. (149.5), (149.6), and (149.7).

Schematically, the following procedure is to be followed:

$$\begin{array}{ll} t_0 : & \{X, Y, Z, \dot{X}, \dot{Y}, \dot{Z}\} \\ & \downarrow \quad \text{Conversion to Keplerian elements} \\ t_0 : & \{a, e, I, -\omega, E_0\} \\ & \downarrow \quad \text{Equation of Kepler, Eq. (149.7)} \\ t_1 : & \{a, e, I, -\omega, E_1\} \\ & \downarrow \quad \text{Conversion to Cartesian elements} \\ t_1 : & \{X, Y, Z, \dot{X}, \dot{Y}, \dot{Z}\} \end{array}$$

The conversion from Keplerian elements to state vector elements was treated in the previous section. For the somewhat more complicated conversion from position and velocity vector to Keplerian representation, the reader is referred to textbooks such as [Escobal, 1976]. Basically we "invert" Eqs. (149.8) and (149.9) by solving for the six elements  $\{a, e, I, -\omega, E\}$  in terms of the six state vector elements.

## 149.4 Orbit of a Satellite in a Noncentral Force Field

The equations of motion for a real satellite are more difficult than suggested by Eqs. (149.8) and (149.9). First of all, we do not deal with a central force field: the earth is not a sphere, nor does it have a radial symmetric density. Second, we deal with other forces, chiefly the gravity of the moon and the sun, atmospheric drag, and solar radiation pressure. Equations (149.8) and (149.9) get a more general meaning if we suppose that a potential function is being generated by the sum of the forces acting on the satellite:

$$V = V_c + V_{nc}^t + V_{\text{sun}}^t + V_{\text{moon}}^t + \cdots \quad (149.11)$$

where  $V_c$  is the central part of the earth's gravitational potential,

$$V_c = \mu/|X| \quad (149.12)$$

and  $V_{nc}^t$  is the noncentral and time-dependent part of the Earth's gravitational field. (The upper index  $t$  has been added to various potentials to reflect their time variability with respect to the inertial frame.)

The equations of motion to be solved are

$$\begin{aligned} \ddot{\mathbf{X}} &= \nabla(V_c + V_{nc}^t + V_{\text{sun}}^t + V_{\text{moon}}^t + \cdots) \\ &= \nabla V_c + \nabla V_{nc}^t + \nabla V_{\text{sun}}^t + \nabla V_{\text{moon}}^t + \cdots \end{aligned} \quad (149.13)$$

For the earth's gravitational field, we have (in an earth-fixed frame)

$$V_c + V_{nc} = \frac{\mu}{r} \left[ 1 + \sum_{l=1}^{\infty} \sum_{m=0}^l \left( \frac{a_e}{r} \right)^l \cdot (C_{lm} \cos m\lambda + S_{lm} \sin m\lambda) \cdot P_{lm}(\sin \phi) \right] \quad (149.14)$$

With Eq. (149.14) one is able to compute the potential at each point  $\{\lambda, \phi, r\}$  necessary for the integration of the satellite's orbit. The coefficients  $C_{lm}$  and  $S_{lm}$  of the spherical harmonic expansion are in the order of  $10^{-6}$  except for  $C_{20}$  ( $l = 2, m = 0$ ), which is about  $10^{-3}$ . This has to do with the fact that the earth's equipotential surface at mean sea level can be best approximated by an ellipsoid of revolution. One has to realize that the coefficients  $C_{lm}, S_{lm}$  describe the shape of the potential field and not the shape of the physical earth, despite a high correlation between the two.  $P_{lm}(\sin \phi)$  are the associated Legendre functions of the first kind, of degree  $l$  and order  $m$ ;  $a_e$  is some adopted value for the semimajor axis (equatorial radius) of the earth. [For values of  $a_e$ ,  $\mu (= GM)$ , and  $C_{20} (= -J_2)$ , see the following: [IAG, 1971](#); [IAG, 1980](#); [IAG, 1984](#); [IAG, 1988a](#); [IAG, 1988b](#); [DMA, 1988](#); [IERS, 1992](#); and [Cohen and Taylor, 1988](#).]

The equatorial radius  $a_e$ , the geocentric gravitational constant  $GM$ , and the dynamic form factor  $J_2$  characterize the earth as an ellipsoid of revolution with an equipotential surface.

If we restrict ourselves to the central part ( $\mu = GM$ ) and the dynamic flattening ( $C_{20} = -J_2$ ),

then Eq. (149.14) becomes

$$V_c + V_{nc} = \frac{\mu}{r} \left[ 1 + \frac{J_2 a_e^2}{2r^2} \cdot (1 - 3 \sin^2 \phi) \right] \quad (149.15)$$

with

$$\sin \phi = \sin \delta = \frac{z}{r} \quad (149.16)$$

where  $\phi$  is the latitude and  $\delta$  the declination (see [Fig. 149.2](#)).

The solution expressed in Keplerian elements shows periodic perturbations and some dominant secular effects. An approximate solution using only the latter effects is (position only)

$$X_I = \mathcal{R}_3[-(\dot{\Omega}_0 + \dot{\Omega} \Delta t)] \cdot \mathcal{R}_1(-I) \cdot \mathcal{R}_3[-(\omega_0 + \dot{\omega} \Delta t)] \cdot X_\omega \quad (149.17)$$

with

$$\Delta t = t - t_0 \quad (149.18)$$

$$\dot{\Omega} = -\frac{3}{2} \frac{J_2 a_e^2}{a^2 (1 - e^2)^2} n \cos I \quad (149.19)$$

$$\dot{\omega} = \frac{3}{2} \frac{J_2 a_e^2}{a^2 (1 - e^2)^2} n (2 - 2^{1/2} \sin^2 I) \quad (149.20)$$

$$n = n_0 \cdot \left[ 1 + \frac{3}{2} \frac{J_2 a_e^2 \sqrt{1 - e^2}}{a^2 (1 - e^2)^2} (1 - 1^{1/2} \sin^2 I) \right] \quad (149.21)$$

with

$$n_0 = \sqrt{\frac{GM}{a^3}} \quad (149.22)$$

Whenever

$I = 0^\circ$	we have	an equatorial orbit
$0^\circ < I < 90^\circ$		a direct orbit
$I = 90^\circ$		a polar orbit
$90^\circ < I < 180^\circ$		a retrograde orbit
$I = 180^\circ$		a retrograde equatorial orbit

Equation (149.19) shows that the ascending node of a direct orbit slowly drifts to the west. For a satellite at about 150 km above the earth's surface, the right ascension of the ascending node decreases about  $9^\circ$  per day.

The satellites belonging to the global positioning system have an inclination of about  $55^\circ$ . Their nodal regression rate is about  $-0.04187^\circ$  per day.

## 149.5 The Global Positioning System (GPS)

---

The Navstar GPS space segment consists of 1 Block I satellite, 9 Block II satellites, and 15 Block IIA satellites as of October 1994 [GPS World, 1994]. This means that the full Block II satellite constellation, in six orbital planes at an height of about 20 000 kilometers, is complete. With this number of satellites, 3-D positioning is possible every hour of the day. However, care must be exercised, since an optimum configuration for 3-D positioning is not available on a full day's basis.

In the meantime, GPS receivers, ranging in cost between \$300 and \$20 000 , are readily available. Over 100 manufacturers are marketing receivers, and the prices are still dropping! Magazines such as *Geodetical Info Magazine*, *GPS World*, *P.O.B.*, and *Professional Surveyor* regularly publish information on the latest models [see, for example, the recent GPS equipment surveys in (Reilly, 1994) and in (Chan and Schorr, 1994)].

GPS consumer markets have been rapidly expanding. In the areas of land, marine, and aviation navigation; of precise surveying; of electronic charting; and of time transfer the deployment of GPS equipment seems to have become indispensable. This holds for military as well as civilian users.

### Positioning

Two classes of positioning are recognized: Standard Positioning Service (SPS) and Precise Positioning Service (PPS). In terms of positional accuracies one has to distinguish between SPS with and without selective availability (SA) on the one hand and PPS on the other. Selective availability deliberately introduces clock errors and ephemeris errors in the data being broadcast by the satellite. The current accuracy of the (civil) signal without SA is in the order of 20-40 m. With SA-implemented SPS accuracy is degraded to 100 m. At the time of this writing (October 1994) the satellite constellation guarantees 100-m SPS accuracy to civilian and commercial users 95% of the time.

In several applications GPS receivers are interfaced with other positioning systems, such as inertial navigation systems (INS), hyperbolic systems, and even automatic braking systems (ABS) in cars.

GPS receivers in combination with various equipment are able to provide the answers to such general questions as [Wells and Kleusberg, 1990]:

All of these questions may refer to an observer either at rest (*static* positioning) or in motion (*kinematic* positioning). The questions may be answered immediately (*real-time* processing, often misnamed DGPS, which stands for differential GPS) or after the fact (*batch* processing).

The various options are summarized in Table 149.1 [Wells and Kleusberg, 1990]. The accuracies for time dissemination are summarized in Table 149.2.

**Table 149.1** Accuracies of Various GPS Positioning Modes

Absolute positioning	
SPS with SA	100 m
SPS without SA	40 m
PPS	20 m
Relative differential positioning	
Differential SPS	10 m
Carrier-smoothed code	2 m
Ambiguity-resolved carrier	10 cm
Surveying between fixed points	1 mm to 10 cm

*Note:* The accuracy of differential modes is dependent on interreceiver distance.

**Table 149.2** Accuracies of Various GPS Time Dissemination Modes

Time and time interval	
With SA	500 ns
Without SA, correct position	100 ns
Common mode, common view	< 25 ns

## Limiting Factors

Physics of the environment, instruments, broadcast ephemeris, and the relative geometry between orbits and networks all form limiting factors on the final accuracy of the results. Dilution of precision (DOP) is used as a scaling factor between the observational accuracy and positioning accuracy [Wells, 1986]. For reasons of safety and accuracy one should avoid periods in which the DOP factor is larger than 6.

The atmosphere of the earth changes the speed and the geometrical path of the electromagnetic signals broadcast by the GPS satellites. In the uppermost part of the atmosphere (the ionosphere) charged particles vary in number spatially as well as temporally. The so-called ionospheric refraction errors may amount to several tens of meters. Since this effect is frequency dependent,

the first-order effect can be largely eliminated by the use of dual-frequency receivers. The lower part of the atmosphere (the troposphere) causes refraction errors of several meters. Fortunately, the effect can be modeled rather well by measuring the atmospheric conditions at the measuring site.

GPS instruments are capable of measuring one or a combination of the following signals:

- C/A code, with an accuracy of a few meters

- P code, with an accuracy of a few decimeters

- Carrier phase, with an accuracy of a few millimeters

In addition to this measurement noise, receiver clock errors have to be modeled as to-be-solved-for parameters. It is this synchronization parameter between satellite time and receiver time that makes it necessary to have at least four satellites in view in order to get a 3-D fix.

Because of the high frequency of the GPS signals, multipath effects may hamper the final accuracy; the signal arriving at the receiver through a reflected path may be stronger than the direct signal. By careful antenna design and positioning, multipath effects are reduced. The phase center of the antenna needs to be carefully calibrated with respect to a geometric reference point on the antenna assembly. However, because of the varying inclination angle of the incoming electromagnetic signals, effects of a moving phase center may be present at all times.

Information on the orbit of the satellite, as well as the orbital geometry relative to the network/receiver geometry, influences the overall positioning accuracy. The information the satellite broadcasts on its position and velocity is necessarily the result of a process of prediction. This causes the broadcast ephemeris to be contaminated with extrapolation errors. Typical values are

- Radial Error: about 5 m

- Across-track error: about 10 m

- Along-track error: about 15 m

Also, the on-board satellite clock is not free of errors. Orbital and satellite clock errors can be largely taken care of by careful design of the functional model.

As mentioned before, deliberate contamination of the broadcast ephemeris and satellite time degrades the system accuracy to several tens of meters. PPS users are able to use the P code on two frequencies and have access to the SA code. Consequently, they are capable of eliminating the ionospheric effects and of removing deliberately introduced orbital and satellite clock errors. The resulting measurement error will be about 5 m. SPS users are able to use the C/A code (on one frequency only); they do not have access to the SA code. Consequently, the ionospheric error can only be roughly modeled, and these users are stuck with the deliberate errors. The resulting measurement error may be as large as 50 m.

Translocation techniques such as having a stationary receiver continuously supporting the other (roving) receivers will reduce the measurement error to well below the 10 m for SPS users.

Differencing techniques applied to the carrier phase measurements are successfully used to

eliminate a wide variety of errors, provided the receivers are not too far apart. In essence, two close-by receivers are influenced almost equally by (deliberate) orbital errors and by part of the atmosphere error. Differencing of the measurements of both receivers will cancel a large portion of the first-order effects of these errors.

## Modeling and the GPS Observables

Developing well-chosen functional models  $F$ , relating the GPS measurements  $\mathbf{L}$  to the modeled parameters  $X$ , enables users to fit GPS perfectly to their needs. A wide class of applications, from monitoring the subsidence of oil rigs in the open sea to real-time navigation of vehicles collecting geoinformation, belong to the range of possibilities opened up by the introduction of GPS.

In satellite geodesy, one has traditionally modeled the state of the satellite—a vector combining the positional ( $X$ ) and the velocity ( $\dot{X}$ ) information. Nowadays GPS provides geodesists, or geoscientists in general, with a tool by which the state of the observer, also in terms of position ( $x$ ) and velocity ( $\dot{x}$ ), can be determined with high accuracy and often in real time. The GPS satellite geodetic model has evolved to

$$\mathbf{L} = F(X, \dot{X}, x, \dot{x}, \mathbf{p}, t) \quad (149.23)$$

with

$\mathbf{L}$  = C/A code, P code, or carrier phase observations,  $i = 1, \dots, n$

$X$  = 3-D position of the satellite at epoch  $t$

$\dot{X}$  = 3-D velocity of the satellite at epoch  $t$

$x$  = 1-D, 2-D, or 3-D position of the observer at epoch  $t$

$\dot{x}$  = 1-D, 2-D, or 3-D velocity of the observer at epoch  $t$

$\mathbf{p}$  = vector of modeled (known or unknown) parameters,  $j = 1, \dots, u$

$t$  = epoch of measurement taking

Various differencing operators  $D^k$ , up to order 3, are applied to the original observations in order to take full benefit of the GPS measurements. The difference operator  $D^k$  may be applied in the observation space spanned by the vector  $\mathbf{L}$  [Eq. (149.24)], or the  $D^k$  operator may be applied in the parameter space  $x$  [Eq. (149.25)]:

$$D^k[\mathbf{L}] = D^k[F(X, \dot{X}, x, \dot{x}, \mathbf{p}, t)] \quad (149.24)$$

$$\mathbf{L} = F(X, \dot{X}, D^1(x, \dot{x}), \mathbf{p}, t) \quad (149.25)$$

The latter method is sometimes referred to as "delta positioning." This is a difficult way of saying that one may either construct so-called derived observations from the original observations by differencing techniques, or model the original observations, compute parameters (e.g., coordinates) in this way, and subsequently start a differencing technique on the results obtained from the roving receiver and the base receiver.

## Pseudo Ranging

We restrict the discussion to the C/A-based pseudo-range observables. The ranges are called "pseudo" because this technique is basically a one-way ranging technique with two independent clocks: the offset  $\delta t_E^S$  between the satellite clock  $S$  and the receiver clock  $E$  yields one additional parameter to be solved for. Writing the observation equation in the earth-fixed reference frame, we have

$$pr = \sqrt{(x^S - x_E)^2 + (y^S - y_E)^2 + (z^S - z_E)^2} - c \cdot \delta t_E^S \quad (149.26)$$

Inspection of the partials,

$$\frac{\partial pr}{\partial x^S} = \frac{x^S - x_E}{pr} = -\frac{\partial pr}{\partial x_E} \quad (149.27)$$

$$\frac{\partial pr}{\partial y^S} = \frac{y^S - y_E}{pr} = -\frac{\partial pr}{\partial y_E} \quad (149.28)$$

$$\frac{\partial pr}{\partial z^S} = \frac{z^S - z_E}{pr} = -\frac{\partial pr}{\partial z_E} \quad (149.29)$$

$$\frac{\partial pr}{\partial(\delta t_E^S)} = -c \quad (149.30)$$

reveals that:

- The coordinates of the stations are primarily obtained in a frame determined by the satellites or, better, by their broadcast ephemeris.
- Partial derivatives evaluated for neighboring stations are practically identical, so the coordinates of one station need to be adopted.

## Phase (Carrier Wave) Differencing

For precise engineering applications the phase of the carrier wave is measured. Two wavelengths are available in principle:

$$\begin{aligned} L_1: \quad \lambda_1 &= \frac{c}{f_1} \quad \text{with } f_1 = 1.57542 \text{ GHz} \\ &\cong 19.0 \text{ cm} \end{aligned} \quad (149.31)$$

and

$$L_2: \quad \lambda_2 = \frac{c}{f_2} \quad \text{with } f_2 = 1.22760 \text{ GHz} \quad (149.32)$$

$$\cong 24.4 \text{ cm}$$

For phase measurements the following observation equation can be set up:

$$\text{Range} = \phi + N \cdot \lambda_l, \quad l = 1, \dots, 2 \quad (149.33)$$

or

$$\Phi_E^S = \sqrt{(x^S - x_E)^2 + (y^S - y_E)^2 + (z^S - z_E)^2} - N_E^S \cdot \lambda_l \quad (149.34)$$

where  $\Phi_E^S$  is the phase observable in a particular  $S$ - $E$  combination, and  $N_E^S$  is the integer multiple of wavelengths in the range: the ambiguity. Phase measurements can be done with probably 1% accuracy. This yields an observational accuracy—in case the ambiguity  $N$  can be properly determined—in the millimeter range!

Using the various differencing operators on the phase measurements:

$D^{k=1}$  yields single differences:

- Between receiver differences,  $\Delta\Phi$ , eliminating or reducing satellite-related errors
- Between satellite differences,  $\nabla\Phi$ , eliminating or reducing receiver-related errors
- Between epoch differences,  $\delta\Phi$ , eliminating phase ambiguities per satellite-receiver combination

$D^{k=2}$  yields double differences:

- Between receiver/satellite differences,  $\nabla\Delta\Phi$ , eliminating or reducing satellite- and receiver-related errors, and so forth

$D^{k=3}$  yields triple differences:

- Between epoch/receiver/satellite differences,  $\delta\nabla\Delta\Phi$ , eliminating or reducing satellite/receiver-related errors, and ambiguities

Receivers that use carrier wave observations have, in addition to the electronic components that do the phase measurements, a counter that counts the complete cycles between selected epochs. GPS analysis software uses the triple differences to detect and possibly repair cycle slips occurring during loss of lock.

Design specifications and receiver selection are dependent on the specific project accuracy requirements. In the U.S. the Federal Geodetic Control Committee has adopted various specifications [FGCC, 1989].

## GPS Receivers

A variety of receivers are on the market. Basically, they can be grouped in the four classes listed in [Table 149.3](#).

**Table 149.3** Accuracy Grades of Civilian/Commercial GPS Receivers

Navigation grade	40–100 m	C/A code, in stand-alone mode
Mapping (GIS) grade	2–5 m	C/A code, in differenced mode
Surveying grade	1–2 cm within 10 km	C/A code + phase, differenced
Geodesy grade	5–15 mm over any distance	C/A + P code + phase, differenced

The observations of the first three types of receivers are subjected to models that can be characterized as *geometric* models. The position of the satellite is considered to be known, based mostly on the information taken from the broadcast ephemeris. The known positions are, of course, not errorless. First of all, the positions are predicted and thus contain errors because of an extrapolation process in time. Second, the positions being broadcast may be corrupted by intentional errors (due to SA). Differencing techniques are capable of eliminating most of the error if the separation between base station and roving receiver is not too large.

Millimeter-accurate observations from geodesy-grade receivers are often subjected to analysis through models of the *dynamic* type. Software packages containing dynamic models are very elaborate and allow for some kind of orbit improvement estimation process.

Reilly [1994] and Chan and Schorr [1994] list overviews of recent GPS receivers and supporting software packages.

## GPS Base Station

GPS, like most other classical survey techniques, has to be applied in a differential mode if one wants to obtain reliable relative positional information. This implies that, for most applications of GPS in geodesy—surveying and mapping, photogrammetry, GIS, and so forth—one has to have at least two GPS receivers at one's disposal. If one of the receivers occupies a known location during an acceptable minimum period, then one may obtain accurate coordinates for the second receiver *in the same frame*. In surveying/geodesy applications it is preferable to include three stations with known horizontal coordinates and at least four with known vertical (orthometric) heights. In most GIS applications a receiver is left at one particular site. This station serves as a so-called base station.

## GIS, Heights, and High-Accuracy Reference Networks

In order to reduce influences from satellite-related errors and atmospheric conditions in geodesy, surveying, and geographic information systems (GIS) applications, GPS receivers are operated in a differential mode. Whenever the roving receiver is not too far from the base station receiver, errors at high altitudes (satellite and atmosphere) are more or less canceled if the "fix from the field" is

differenced with the "fix from the base."

The Washington editor of *GPS World*, Hale Montgomery, writes, "As a peripheral industry, the reference station business has grown almost into an embarrassment of riches, with stations proliferating nationwide and sometimes duplicating services." William Strange, Chief Geodesist at The National Geodetic Survey (NGS), is quoted as saying, "Only about 25 full-service, fixed stations would be needed to cover the entire United States" [Montgomery, 1993]. A group of the interagency Federal Geodetic Control subcommittee has compiled a list of about 90 base stations operating on a more or less permanent basis. If all GIS/GPS base stations being planned or in operation are included, the feared proliferation will be even larger. From the point of view of the U.S. tax-paying citizen, "duplication of services" may be wasteful; on the other hand, decentralization of services may often be more cost-effective than all-encompassing projects run by even more all-encompassing agencies.

#### GEOGRAPHIC INFORMATION SYSTEMS: THE BASICS

Geographic Information Systems are databases that store both location information and descriptive data. This information can be displayed in a computerized map format. Most GIS databases store features in a layer format so that different types of information can be sorted, searched, edited, displayed, and output by type.

In this simple example, various types of data that relate to an urban asset management database are depicted. However, any type of geographic data could be stored and organized this way in a GIS. Here, three layers of a database are shown: a road map, an underground power line map on the middle layer, and street light poles on the third layer. Both the location data and descriptive information, such as road type, pole condition, and cable type, can be gathered with GPS and easily transferred to this GIS.

### **How GPS Works**

The Global Positioning System is a constellation of 24 satellites that orbit the earth at an altitude of 20 200 kilometers, constantly emitting GPS signals. GPS receivers on earth calculate their positions by making distance measurements to four or more satellites. Individual distance measurements to each satellite are determined by analyzing the time it takes for a signal to travel from a satellite, whose location is known through monitoring, to a GPS receiver. Using some relatively simple geometry, the receiver determines its position. GPS mapping systems utilize Differential GPS (DGPS) techniques to obtain even better accuracy, in the decimeter to 5-meter range. (Courtesy of Trimble Navigation.)

From the geodetic point of view, the duplication of services (base station-generated fixes in the field) will proliferate the coordinate fields and the reference frames they supposedly are tied to. The loss of money and effort in the years to come in trying to make sense out of these most likely nonmatching point fields may be far larger than the money lost in "service-duplicating" base stations. If we are not careful, the "coordinate-duplicating" base stations will create a chaos among GIS-applying agencies.

Everyone is convinced of the necessity to collect GIS data in one *common frame*. Formerly, the GIS community was satisfied with positions of 3- to 5-m accuracy. Manufacturers are aggressively marketing GPS/GIS equipment with 0.5-m accuracy (with a price tag of 20 000 per receiver, and remember you need at least two). The increased demand for accuracy requires that a reference frame be in place that lasts at least two decades. This calls for a consistent reference that is one and probably two orders of magnitude more accurate than presently available.

The accuracy of the classical horizontal control was on the order of one part in 100 000 (1 cm over 1 km). GPS is a survey tool with an accuracy of one part per 1 000 000 (1 cm over 10 km). Many states have put new high-accuracy reference networks (HARNs) in place to accommodate the accuracy of GPS surveys. Even for GIS applications where 0.5-m accuracies are claimed for the roving receivers, one may speak of 1 ppm surveys whenever those rovers operate at a distance of 500 km from their base station.

It should not be forgotten that GPS is a geometric survey tool yielding results in terms of earth-fixed coordinate differences  $x_{ij}$ . From these coordinate differences expressed in curvilinear coordinates we obtain at best somewhat reproducible ellipsoidal height differences. These height differences are *not* easily converted to orthometric height differences of equal accuracy. The latter height differences are of interest in engineering and GIS applications, as discussed in the next section.

## 149.6 Gravity Field and Related Issues

### One-Dimensional Positioning: Heights and Vertical Control

Some of the most accurate measurements surveyors are able to make are the determinations of height differences by spirit leveling. Since a leveling instrument's line of sight is tangent to the potential surface, one may say that leveling actually determines the height differences with respect to equipotential surfaces. If one singles out one particular equipotential surface at mean sea level (the so-called geoid), then the heights a surveyor determines are actually *orthometric heights* (see Fig. 149.3).

**Figure 149.3** Orthometric heights.

Leveling in a closed loop is a check on the actual height differences not in a metrical sense but in a potential sense: the distance between equipotential surfaces varies due to local gravity variations.

In spherical approximation the potential at a point A is

$$V = -\frac{GM}{r} = -\frac{GM}{R + h} \quad (149.35)$$

The gravity is locally dependent on the change in the potential per height unit,  
or

$$\frac{dV}{dr} = g = \frac{GM}{r^2} \quad (149.36)$$

The potential difference  $dV$  between two equipotential surfaces is

$$dV = g \cdot dr \quad (149.37)$$

Consequently, if one levels in a loop, one has

$$\sum dV = \sum g \cdot dr = 0 \quad (149.38)$$

or

$$\oint dV = \oint g \cdot dr = 0 \quad (149.39)$$

This implies that for each metrically leveled height difference  $dr$ , one has to multiply this difference by the local gravity. Depending on the behavior of the potential surfaces in a certain area and the diameter of one's project, one has to "carry along a gravimeter" while leveling.

The variations of local gravity vary depending on the geology of the area. Variations in the order  $10^{-7}g$  may yield errors as large as 10 mm for height differences in the order of several hundred meters. For precise leveling surveys ( $\leq 0.1$  mm/km), gravity observations have to be made with an interval of:

2 to 3 km in relatively "flat" areas

1 to 2 km in hilly terrain

1/2 to 1 1/2 km in mountainous regions

For more design criteria on leveling and gravity surveys, see [FGCC, 1989] and Table 149.4.

**Table 149.4** FGCC Vertical Control Accuracy Standards (Differential Leveling)

First Order		
Class I		$b^* < 0.5$
Class II		0.7
Second Order		
Class I		1.0
Class II		1.3
Third Order		
		2.0

$*b = S/\sqrt{d}(\text{mm}/\sqrt{\text{km}})$ , where

S = standard deviation of elevation difference between control points (mm)

d = approximate horizontal distance along leveled route (km)

GPS surveys yield at best ellipsoidal height differences. These are rather meaningless from the engineering point of view. Therefore, extreme caution should be exercised when GPS height

information, even after correction for geoidal undulations, is to be merged with height information from leveling. For two different points  $i$  and  $j$ ,

$$h_i = H_i + N_i \quad (149.40)$$

$$h_j = H_j + N_j \quad (149.41)$$

Subtracting Eq. (149.40) from (149.41), we find the ellipsoidal height differences  $h_{ij}$  (from GPS) in terms of the orthometric height differences  $H_{ij}$  (from leveling) and the geoidal height differences  $N_{ij}$  (from gravity surveys):

$$h_{ij} = H_{ij} + N_{ij} \quad (149.42)$$

where

$$h_{ij} = h_j - h_i \quad (149.43)$$

$$H_{ij} = H_j - H_i \quad (149.44)$$

$$N_{ij} = N_j - N_i \quad (149.45)$$

For instance, with the National Geodetic Survey's software program GEOID93 geoidal height differences are as accurate as 10 cm over 100 km for the conterminous U.S. For GPS leveling, this means that GPS may compete with third-order leveling as long as the stations are more than 5 km apart.

In principle, any equipotential surface can act as a vertical datum. The National Geodetic Vertical Datum of 1929 (NGVD29) is not a true mean sea-level datum. Problems may arise in merging GPS heights, gravity surveys, and orthometric heights referring to NGVD29. Heights referring to the NGVD88 datum will be more suitable for use with GPS surveys. In the U.S. about 600 000 vertical control stations are in existence.

## Two-Dimensional Positioning: East/North and Horizontal Control

In classical geodesy the measurements in height (leveling) had to be separated from the horizontal measurements (directions, angles, azimuths, distances). To allow for the curvature of the earth and the varying gravity field, the horizontal observations were reduced first to the geoid, taking into account the orthometric heights. Subsequently, it was desired to take advantage of geometrical properties between the once-reduced horizontal observations, and the observations had to be reduced once more, from the geoid to the ellipsoid. An ellipsoid approximates the geoid up to 0.01%; the variations of the geoid are nowhere larger than 150 m. On the ellipsoid, which is a precise mathematical figure, one could check, for instance, whether the sum of the three angles equaled a prescribed value.

So far, geodesists have relied on a biaxial ellipsoid of revolution. A semimajor axis  $a_e$  and a

semiminor axis  $b_e$  define the dimensions of the ellipsoid. Rather than using this semiminor axis, one may specify the flattening of the ellipsoid:

$$f = \frac{a_e - b_e}{a_e} \approx \frac{1}{298.257 \dots} \quad (149.46)$$

For a semimajor axis of about 6378.137 km, this implies that the semiminor axis is  $6378.137/298.257 \approx 22$  kilometers shorter than  $a_e$ .

Distance measurements need to be reduced to the ellipsoid. Angular measurements made with theodolites, total stations, and other instruments need to be corrected for several effects:

- The direction of local gravity does not coincide with the normal to the ellipsoid.
- The direction of the first axis of the instrument coincides with the direction of the local gravity vector. Notwithstanding this effect, the earth's curvature causes nonparallelism of first axes of one arcsecond for each 30 m.
- The targets aimed at generally do not reside on the ellipsoid.

The noncoincidence of the gravity vector and the normal is called "deflection of the vertical." Proper knowledge of the behavior of the local geopotential surfaces is needed for proper distance and angle reductions. Consult Vanicek and Krakiwsky [1982], for example, for the mathematical background of these reductions. The FGCC adopted the accuracy standards given in Table 149.5 for horizontal control using classical geodetic measurement techniques [FGCC, 1984]. In the U.S. over 270 000 horizontal control stations exist.

**Table 149.5** FGCC Horizontal Control Accuracy Standards (Classical Techniques)

First Order	
1:100 000 (10 mm/km)	
Second Order	
Class I	1:50 000 (20 mm/km)
Class II	1:20 000 (50 mm/km)
Third Order	
Class I	1:10 000 (100 mm/km)
Class II	1:5 000 (200 mm/km)

## Three-Dimensional Positioning: Geocentric Positions and Full 3-D Control

Modern 3-D survey techniques, most noticeably GPS, allow for immediate 3-D relative positioning. 3-D coordinates are equally accurately expressed in ellipsoidal, spherical, or Cartesian coordinates. Care should be exercised to properly label curvilinear coordinates as spherical (geographic) or ellipsoidal (geodetic). Table 149.6 shows the large discrepancies between the two.

At the mid-latitudes they may differ by more than 11'. This could result in a north-south error of 20 km. When merging GIS data sets one should be aware of the meaning "LAT/LON" in any instance. Consult [Stem, 1991] for the use of U.S. state plane coordinates. Curvilinear coordinates, their transformations, and their use are discussed in a variety of textbooks; see the section "Further Information" or articles such as [Soler, 1976], [Leick and van Gelder, 1975], [Soler and Hothem, 1988], and [Soler and van Gelder, 1987].

**Table 149.6** Geographic (Spherical) Latitude as a Function of Geodetic Latitude

Geodetic Latitude			Geographic Latitude			Geodetic Minus Geographic Latitude		
Degrees	Minutes	Seconds	Degrees	Minutes	Seconds	Degrees	Minutes	Seconds
00	0	0.000	00	00	00.000	00	00	00.000
10	0	0.000	09	56	03.819	00	03	56.181
20	0	0.000	19	52	35.868	00	07	24.132
30	0	0.000	29	50	01.089	00	09	58.911
40	0	0.000	39	48	38.198	00	11	21.802
50	0	0.000	49	48	37.402	00	11	22.598
60	0	0.000	59	49	59.074	00	10	00.926
70	0	0.000	69	52	33.576	00	07	26.424
80	0	0.000	79	56	02.324	00	03	57.676
90	0	0.000	90	00	00.000	00	00	00.000

Despite their 3-D characteristics, networks generated by GPS are the weakest in the vertical component, not only because of the lack of physical significance of GPS's determined heights, as described in the preceding subsection, but also because of the geometrical distribution of satellites with respect to the vertical: no satellite signals are received from "below the network." This lopsidedness makes the vertical the worst determined component in 3-D.

Because of the inclination of the GPS satellites there are places on earth, most notoriously the mid-latitudes, where there is not an even distribution of satellites in the azimuth sense. For instance, in the northern mid-latitudes we never have as many satellites to the north as we have to the south [see, for example, (Santerre, 1991)]. This makes the latitude the second best determined curvilinear coordinate. For space techniques the FGCC has proposed the classification in Table 149.7.

**Table 149.7** FGCC 3-D Accuracy Standards (Space System Techniques)

AA Order (Global)
3 mm + 1: 100 000 00 (1 mm/100 km)
A Order (Primary)
5 mm + 1: 10 000 000 (1 mm/10 km)
B Order (Secondary)
8 mm + 1: 1 000 00 (1 mm/km)
C Order (Dependent)
10 mm + 1: 100 000 (10 mm/km)

## Surveying Applications for Geographic Information Systems

---

- 150.1 GIS Fundamentals
- 150.2 Monumentation or Control Surveying
- 150.3 Topographic Surveying
- 150.4 Future GIS Surveying Applications

**James F. Thompson**

*Thompson Professional Group, Inc.*

The utilization of **geographic information systems** (GISs) for the facility management of information and data has become widespread throughout the U.S. and the rest of the world. Inherently, a GIS can be quite complex in terms of the amount of data to be managed; however, the accuracy and usefulness of a given GIS is directly related to the quality and quantity of information and data properly collected, input, and managed within the system itself.

There are several ways that information and data can be obtained for a GIS. These would include such means as the digital input of information from previously prepared maps, plans, and so forth, and many other methods of data collection and input that can involve remote sensing and the routine communication of relational databases. But usually, the foundation and fundamental building blocks of a GIS are based upon the surveying applications utilized for the system.

This chapter discusses the various land surveying applications for GISs and the most commonly used techniques for collecting the field information. Future applications as based upon ever-developing technology are discussed as well.

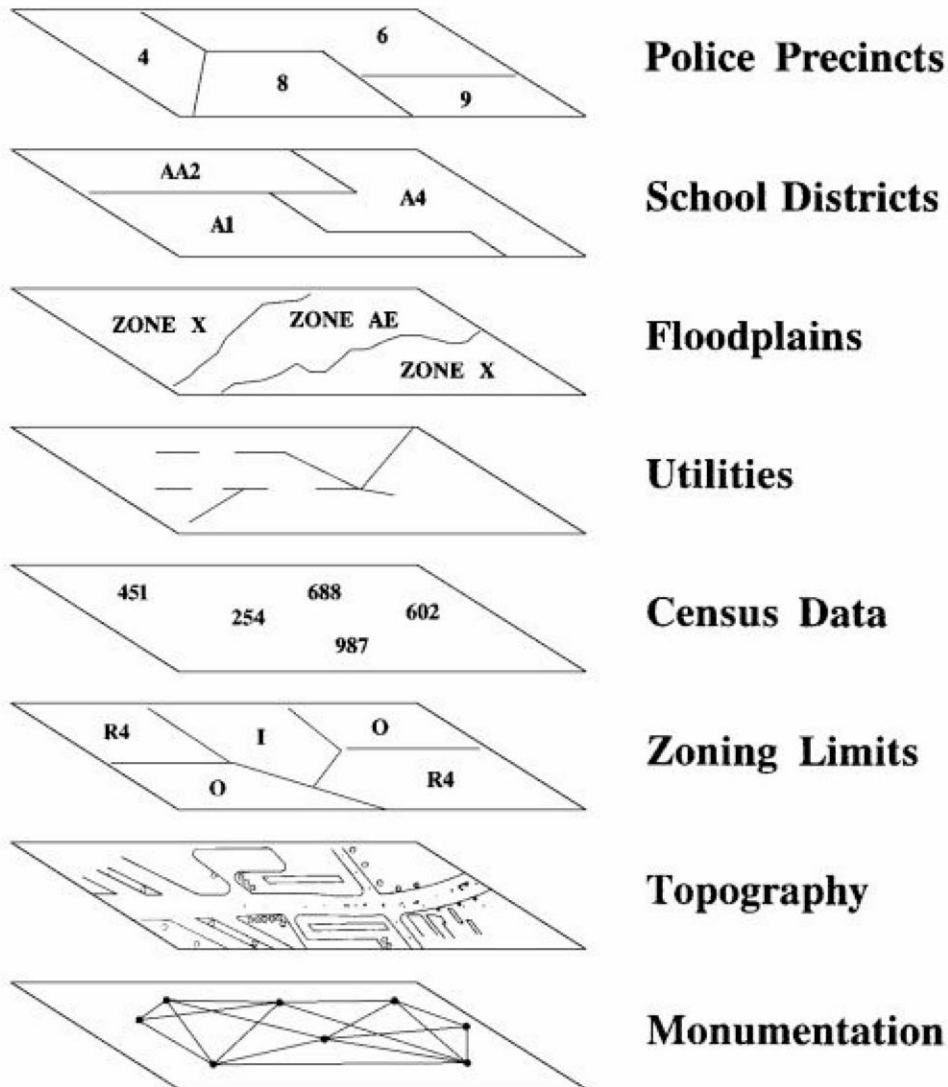

### 150.1 GIS Fundamentals

---

A GIS can be generally described as a computer-based system that stores and manages information and data as related to a geographic area. In other words, data are managed by a graphic computer system to readily provide information on a specific geographic point or area of interest. A GIS is typically divided into graphic layers or levels to better manage the information. [Figure 150.1](#) represents a simple GIS configuration where information of different types is *stacked* to form an organizational structure for the system itself. This graphic information is linked to one or more databases to form a relationship between the graphic information and supporting data. Within a GIS every graphic element, together with its supporting data or attributes, has its own unique geographic coordinates. As such, a GIS can be used to query a database and find information on a

geographic feature, element, or area.

**Figure 150.1** Simplified GIS layers.

The complete discussion of the GIS subject matter can be quite involved and is beyond the scope of this chapter. What is important to note is that the fundamental geographic information itself is based upon the *surveying* data used as the foundation of the GIS. This surveying information can be assembled as based purely on existing plats, maps, and so forth without any detailed field work; however, these "paper surveys" typically will not yield an accurate reflection of existing conditions. It is extremely important that a GIS be founded and maintained on solid and accurate surveying information, because the unique address of a given graphic element will only be as accurate as the overall surveying methods employed for the development of the GIS.

Although there are certainly several distinct categories of surveying, there are two fundamental

land surveying categories that are commonly and easily applied to a GIS. The first is **monumentation** (or control) **surveying**, and the second is **topographic surveying**. Each has a vital function in the development of a GIS and plays a significant role in establishing the inherent accuracy of a GIS. In addition, both categories are directly linked, as further discussed in the following sections.

## 150.2 Monumentation or Control Surveying

---

This singular subject of establishing a monumentation network is one of the most important issues relating to the surveying applications for a GIS. The monumentation network is the first building block of a GIS and sets the accuracy standard for the remaining information to be compiled and managed within the system. Should the level of accuracy of the monumentation network be compromised, the remaining surveying information obtained will be at least as inaccurate, since this other information will be slaved to the control network.

A monumentation system for a GIS is a network of control points or monuments, established in the field, that are referenced not only to each other, but also to a common datum. This common datum, in the U.S., is typically that which has already been established by the National Geodetic Survey (NGS) of the federal government. The NGS has established and maintains a network of first-order monuments with assigned horizontal coordinates across the country. In the past first-order was conventionally thought of as having an accuracy level of 1 part in 100000; however, with the advancements in surveying equipment technology, first-order monuments commonly have a much higher level of accuracy. In addition, vertical elevation information is often available for many NGS monuments. It is important to understand that these NGS monuments provide a common thread that bonds geographic areas across the country. Each state has its own coordinate system, as dependent upon the map projection used, which is generally a result of the shape of the state or area to be projected. **Map projections** form the basis for planar mapping of geographic areas. A surveyor establishing the monumentation network for a given area must be knowledgeable of the projection and resultant **state plane coordinate system** used in the area.

When we establish a geodetic monumentation network for a GIS, we are typically densifying the existing NGS monumentation system in our area of interest. Often, many NGS monuments are recovered in the field and then used as reference points within the densified monumentation network. The result of the monumentation survey is a network of readily identifiable points throughout an area that can be easily used for land surveying and **aerial photogrammetry**. The fundamental issue at hand is that, once the monumentation network is established, a common datum will exist throughout an area that can be used to reference all subsequent surveying data. Even past surveying information can be moved to this newly established datum via a coordinate transformation.

The actual procedures for establishing a geodetic monumentation network can be divided into several stages that build upon each other:

1. Research existing NGS monuments and field recover the monuments.
2. Design a network layout as referenced to the recovered NGS monuments.

3. Plan the field survey activities to establish the monuments.
4. Execute the field survey activities.
5. Mathematically adjust the network and calculate the coordinates of the monuments.

Recovering the existing NGS monuments in the field can be very time consuming and, at times, frustrating. Many monuments have not been recovered or used for several years, thus often making them difficult to find. Once recovered, these NGS monuments and their previously established coordinates will be used to reference and constrain the new monuments to be established.

Once the positions of the recovered NGS monuments are known in relation to the area of interest to serve as the geographic region supported by a GIS, a monumentation network is designed that provides the layout of the new monuments. This layout is composed of the existing NGS monuments, the new monuments to be established, and the base lines connecting all of the monuments. The strength and accuracy of a monumentation network is dependent on the design of the layout and, specifically, the base lines within the layout. Today, the most common means used to perform the survey for the establishment of a geodetic monumentation network is the **global positioning system** (GPS). GPS surveying is a method of using transmitting satellites and portable field receivers to accurately determine the coordinates of a point. (GPS surveying is discussed in detail in **Chapter 149**.) A base line between two monuments is created when separate GPS receivers are set on both points and they receive credible satellite data simultaneously. [Figure 150.2](#) illustrates a designed and successfully implemented base-line and monument layout for a municipal GIS application. In the design of the network layout, consideration must be given to the field procedures required to create the needed base lines throughout the monumentation network.

**Figure 150.2** Base-line and monument layout for a municipal GIS application.

Once the desired monumentation layout is designed, the field activities themselves must be carefully planned. Without proper planning, the GPS field surveys can be disastrous. Assuming that all goes well during the GPS field surveys and that good data were received from the satellites,

the resultant coordinates of the new monuments can be calculated. This entire process is often called *balancing*, *adjusting*, or *constraining* the network. During this process, the entire monumentation network is referenced to the NGS datum, and state plane coordinates are assigned to each monument. State plane coordinates differ from surface coordinates as would be needed for conventional plane table land surveying. Notice that state plane coordinates are used in map projections to account for the curvature of the earth. Every point has a scale factor that must be applied to the state plane coordinates (northing and easting) of that point to convert the point's state plane coordinates to surface coordinates at sea level. To account for the difference of the terrain's elevation that normally differs from sea level, a sea level correction factor must be applied as well. The combination of a scale factor and a sea level correction factor is commonly termed a **combined scale factor**. The following equations are used to convert state plane coordinates to surface coordinates:

$$\text{Combined scale factor} = \text{Scale factor} \times \text{Sea level correction factor}$$

$$\text{Surface coordinate} = \text{State plane coordinate} / \text{Combined scale factor}$$

It is extremely important that the relationship between surface and state plane coordinates is understood. A conventional land surveyor does not measure distances, for example, along the map projection utilized, but, rather, along the true terrain surface being surveyed.

After the horizontal coordinates of the monuments are established, vertical elevations can be determined for the points, such as to support surveys that are in need of relational elevations. Once again, a similar method of balancing or adjusting the network is utilized as based upon the known elevations of points within the monumentation network. Many advancements have been made in accurately calculating vertical elevations using GPS surveying. This is mostly a result of the ability to more accurately account for the true shape of and anomalies in the earth's surface. Although GPS surveying is a good technique to use for establishing the vertical elevations of monuments within a network, conventional field surveying or leveling between the monuments is common and works well.

## 150.3 Topographic Surveying

---

The actual collection of field information that shall be used in a GIS is performed through topographic surveying. The category of topographic surveying as applied to a GIS also generally includes other categories of surveys, such as route, utility, and location surveys. The data collected from such a survey include not only the location of surface features (such as telephone poles, streets, trees, rivers, buildings, houses, and other readily identifiable surface topographic features) but also the rights-of-way, easements, property ownership lines, and underground utilities (such as pipelines and sewers). In a sense, the surveyor is the *eyes* of a GIS. What the surveyor includes in the survey in terms of topography, utilities, property corners, and so forth will dictate how much information is available within the GIS. As such, it is important to include as much information as desired or needed in the topographic surveys, which will serve to feed required data to the GIS. As future needs arise, more topographic information can be obtained and included in a GIS.

The methods used to perform topography surveying can vary tremendously. The most common method used is conventional land surveying; however, even that method has changed dramatically with advanced technology. Electronic data collectors (in lieu of hand-written field books) are quite common today, and even GPS receivers are being used routinely in topography surveys. In conjunction with conventional land surveys, aerial photogrammetry is used extensively to obtain topographic information needed to supply data to a GIS. Although conventional land surveying and aerial photogrammetry are some of the most popular means of collecting topographic data for GIS applications, other methods, such as **satellite imagery**, are applied as well.

In performing a conventional topographic survey, a surveyor will traverse between the geodetic network monuments, obtaining as much topographic information as desired. Again, the information sought is dependent on the demands of the GIS that dictate the detail needed in terms of the survey data obtained. The traversed line of the survey between the monuments is balanced in terms of angles and distances as based upon the known coordinates of the monuments; this will ensure that coordinates of the obtained topographic features are properly determined in relation to the datum used for the GIS. [Figure 150.3](#) represents a series of points obtained for a GIS using conventional topographic surveying techniques. [Figure 150.4](#) illustrates the same data in their final form, as would be input graphically into the GIS. Every point has its own unique address and attribute. A fire hydrant, for example, will have its own specific coordinates. A relational database can be linked to the fire hydrant graphic element within the GIS—which would provide such information as when the hydrant was installed and when last checked to ensure its proper operating condition.

**Figure 150.3** Series of points obtained using conventional topographic surveying techniques.

**Figure 150.4** Points converted to topographic features to be input graphically into a GIS.

Aerial photogrammetry, an extremely powerful and cost-effective method of obtaining a great amount of topographic information, is used routinely in GIS applications with conventional land surveying. Like the ground surveys performed, the aerial surveys are linked to the GIS monumentation network by referencing the aerial photographs to known points on the ground that can be clearly identified in the photographs. This is typically done by painting (or in many cases, taping) a large white or contrasting colored mark on the ground in the shape of an "X" or a "V" that can be clearly identified in the photograph. These marks are then tied to the monument system conventionally with ground surveys. The end result is an aerial photograph, or series of photographs, rectified to accurately illustrate the existing topography on the proper coordinate system. Once the aerial photographs are produced, they are digitized into graphic elements that are directly incorporated into a GIS. With the horizontal position of the topographic features, the elevation contours and many specific point elevations can be determined as well.

A combination of conventional land surveys and aerial photogrammetry can be used quite effectively in obtaining most of the topographic features needed for a given GIS application; however, other more advanced surveying methods such as radar and satellite observations can be employed as well. Everything from the broad expanse of wooded areas to the finite detail of utility locations can be surveyed, identified, and incorporated into a GIS. A visionary approach should be

taken regarding the surveying applications of a GIS. It is this approach that will drive the accuracy and integrity of the GIS itself.

## 150.4 Future GIS Surveying Applications

---

When dealing with constantly evolving technology, it often seems that the future is already upon us. In the not-too-distant future, it is expected that GIS technology will be so widespread that essentially every area of the country will be included into a GIS in some fashion. Cities will be linked with other cities, states with other states, and countries with other countries. Automobiles will travel without human interface, because every road and highway will have its route defined with pinpoint accuracy. Every home, building, fence corner, and manhole will have its own unique address in terms of coordinates. All of this information, as managed by a GIS, must be originally established and properly maintained by the surveyor. Hopefully, this task will be made easier by surveying methods of the next generation, which might include handheld survey transceivers and other advanced technologies.

### Defining Terms

**Aerial photogrammetry:** The surveying of surface features through the use of photographs, as taken from an aerial perspective (i.e., an airplane).

**Combined scale factor:** A factor that can be used to convert state plane coordinates to surface terrain coordinates, considering the map projection utilized and the relative elevation of the point of interest.

**Geographic information system:** A computer-based system that stores and manages information and data as related to a geographic area.

**Global positioning system:** A method of surveying that uses transmitting satellites and portable field receivers to accurately determine the coordinates of a point.

**Map projection:** The projection of the earth's surface to a plane (or map), considering the curvature of the earth.

**Monumentation surveying:** The establishment or recovery of a horizontal and/or vertical coordinate control network as based upon a layout of monuments or control points.

**Satellite imagery:** Images of the earth's surface as obtained from orbiting satellites.

**State plane coordinate system:** A coordinate system used throughout the U.S. that is based on the map projection of one or more zones within each state.

**Topographic surveying:** The surveying of topographic features through conventional land surveying, aerial photogrammetry, or other means.

**Remote sensing** involves the use of airborne and space-imaging systems to inventory and monitor earth resources. Broadly defined, remote sensing is any methodology employed to study the characteristics of objects from a distance. Using various remote sensing devices, we remotely collect *data* that can be analyzed to obtain *information* about the objects, areas, or phenomena of interest. This chapter discusses sensor systems that record energy over a broad range of the **electromagnetic spectrum**, from ultraviolet to microwave wavelengths.

Remote sensing affords a practical means for frequent and accurate monitoring of the earth's resources from a site-specific to global basis. This technology is aiding in assessing the impact of a range of human activities on our planet's air, water, and land. Data obtained from remote sensors have provided information necessary for making sound decisions and formulating policy in a host of resource development and land use applications. Remote sensing techniques have also been used in numerous special applications. Expediting petroleum and mineral exploration, locating forest fires, providing information for hydrologic modeling, aiding in global crop production estimates, monitoring population growth and distribution, and determining the location and extent of oil spills and other water pollutants are but a few of the many and varied applications of remote sensing that benefit humankind on a daily basis. It should be pointed out that these applications almost always involve some use of **ground truth** or on-the-ground observation. That is, remote sensing is typically a means of extrapolating from, not replacing, conventional field observation.

## 151.1 Electromagnetic Energy

The sun and various other sources radiate electromagnetic energy over a range of wavelengths. Light is a particular type of **electromagnetic radiation** that can be seen or sensed by the human eye. All electromagnetic energy, whether visible or invisible, travels in the form of sinusoidal waves. Wavelength ranges of special interest in remote sensing are shown in [Table 151.1](#).

**Table 151.1** Components of the Electromagnetic Spectrum

Wavelength	Spectral Region
0.3 to 0.4 $\mu\text{m}$	Ultraviolet
0.4 to 0.7 $\mu\text{m}$	Visible: 0.4 to 0.5 $\mu\text{m}$ = blue 0.5 to 0.6 $\mu\text{m}$ = green 0.6 to 0.7 $\mu\text{m}$ = red
0.7 to 1.3 $\mu\text{m}$	Near infrared
1.3 to 3.0 $\mu\text{m}$	Mid-infrared
3 to 14 $\mu\text{m}$	Thermal infrared
1 mm to 1 m	Microwave

When electromagnetic energy is incident upon an object on the earth's surface, it can interact with the object in any or all of three distinct ways. The incident energy can be reflected, transmitted, or absorbed. The absorbed component goes into heating the body and is subsequently re-emitted from the object. The particular mix of these three possible interactions is dependent upon the physical nature of objects. For example, healthy vegetation normally appears green because the blue and red components of the incident light are absorbed by chlorophyll present in plant leaves. In contrast, concrete surfaces strongly reflect blue, green, and red wavelengths nearly equally and appear light gray. Remote sensors record such variations in energy interaction (both in visible and invisible wavelengths) in order to discriminate between earth surface features and to assist in quantifying their condition.

All objects at a temperature greater than absolute zero radiate energy according to the formula

$$M = \sigma \varepsilon T^4 \quad (151.1)$$

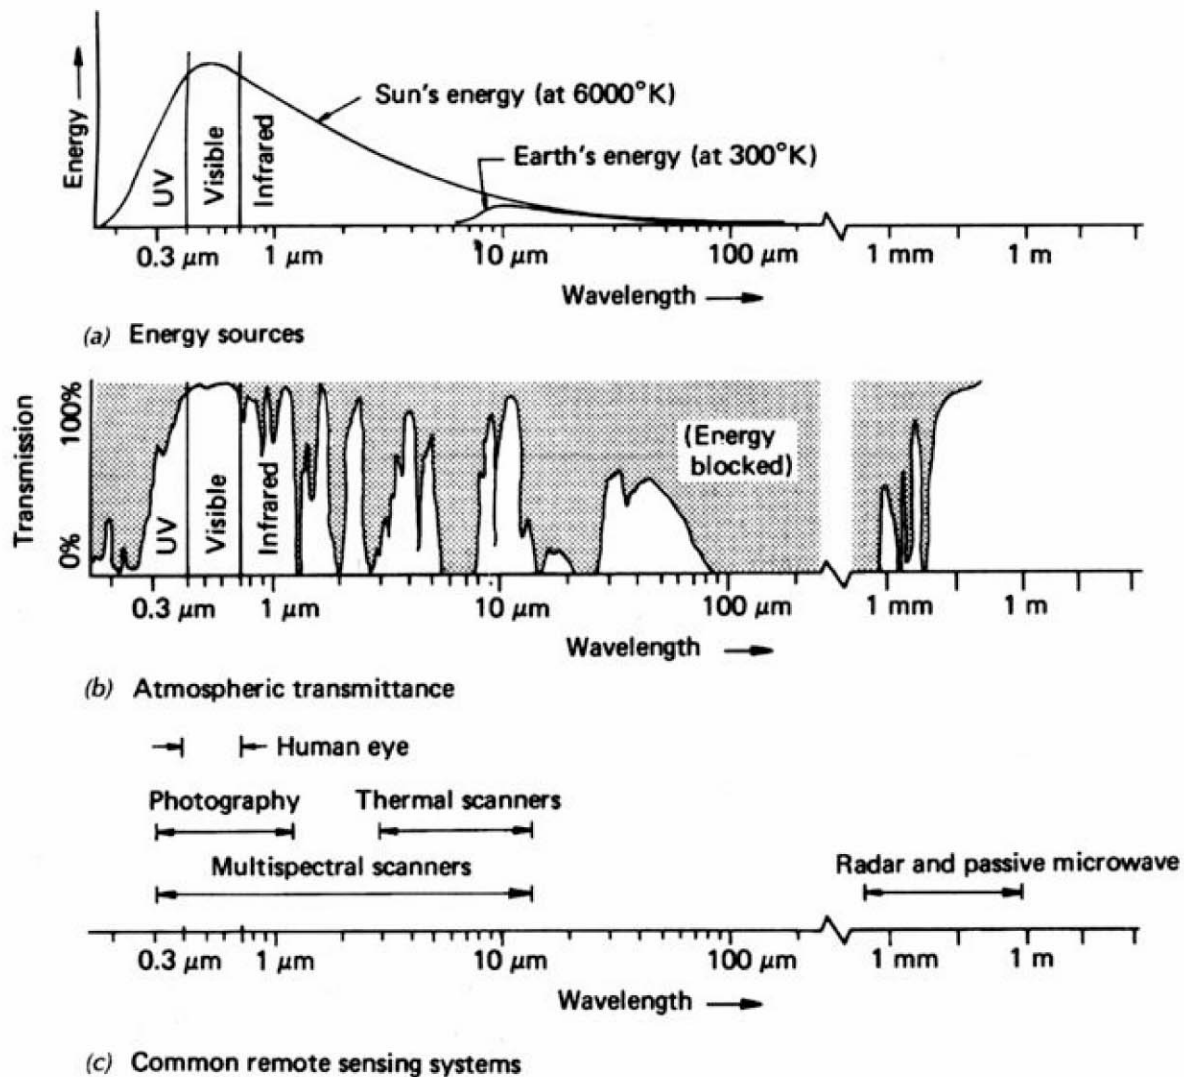

where  $M$  is the total radiant exitance (radiated energy) from the surface of a material ( $\text{W m}^{-2}$ ),  $\sigma$  is the *Stefan-Boltzmann constant* ( $5.6697 \cdot 10^{-8} \text{ W m}^{-2} \text{ K}^{-4}$ ),  $\varepsilon$  is the emissivity (efficiency of radiation) of the material, and  $T$  is the absolute temperature (K) of the emitting material. The general shape of the resulting curves of **emitted energy** (radiant exitance) versus wavelength is shown in [Fig. 151.1\(a\)](#). The wavelength at which the amount of emitted energy is a maximum is related to its temperature by *Wien's displacement law*, which states that

$$\lambda_m = \frac{A}{T} \quad (151.2)$$

where  $\lambda_m$  is the wavelength of maximum spectral radiant exitance ( $\mu\text{m}$ ),  $A = 2898 \mu\text{m K}$ , and  $T$  = temperature (K). Note that the sun's energy has a peak wavelength of  $0.48 \mu\text{m}$  (in the visible part

of the spectrum), whereas the earth's energy has a peak wavelength of  $9.67 \mu\text{m}$  (invisible to the human eye, but able to be sensed by a thermal scanner).

**Figure 151.1** Spectral characteristics of (a) energy sources, (b) atmospheric effects, and (c) sensing systems. Note that wavelength scale is logarithmic. (Source: Lillesand, T. M. and Kiefer, R. W. 1994. *Remote Sensing and Image Interpretation*, 3rd ed. John Wiley & Sons, New York. With permission.)

**Reflected energy** is recorded when objects are sensed in sunlight in the ultraviolet, visible, near-infrared or mid-infrared portions of the spectrum. Radiated energy is recorded in the thermal infrared portion of the electromagnetic spectrum using radiometers and thermal scanners. This allows, for example, the detection and recording of the heated effluent from a power plant as it flows into a lake at a cooler temperature.

Remote sensing systems can be active or passive systems. The examples cited earlier are passive

systems in that they record reflected sunlight or emitted radiation. Radar systems are called *active systems* because they supply their own energy. Pulses of microwave energy are transmitted from radar systems toward objects on the ground, and the backscattered energy is then received by radar antennas and used to form images of the strength of the radar return from various objects.

## 151.2 Atmospheric Effects

---

Because the atmosphere contains a wide variety of suspended particles, it offers energy interaction capabilities just as "ground" objects do. The extent to which the atmosphere transmits electro-magnetic energy is dependent upon wavelength, as shown in [Fig. 151.1\(b\)](#). The sensing systems typically used in various wavelength ranges are shown in [Fig. 151.1\(c\)](#). Energy in the ultraviolet wavelengths is scattered greatly, which limits the use of ultraviolet wavelengths from aerial or space platforms. The atmosphere is transparent enough in the visible, near-infrared, and mid-infrared wavelengths to permit aerial photography and multispectral sensing in these wavelengths. In this region the blue wavelengths are scattered the most and the mid-infrared wavelengths are scattered the least. In the thermal infrared region there are two "windows" where the atmosphere is relatively transparent: 3–5  $\mu\text{m}$  and 8–14  $\mu\text{m}$  wavelength (most aerial thermal scanning is done in the 8–14  $\mu\text{m}$  band). At microwave wavelengths the atmosphere is extremely transparent, and many radar systems can be operated in virtually all weather conditions.

## 151.3 Remote Sensing Systems

---

### Aerial Photography

Aerial photographs can be taken on any of several film types, from a variety of flying heights. Mapping cameras typically use an image size of 230 by 230 mm. Smaller-format cameras (70 mm and 35 mm) can be used where large-area coverage with great geometric fidelity is not required. The interpretability of aerial photographs is highly dependent on the selection of film type and image scale.

Principally because of cost considerations, the films most widely used for aerial photography are the black and white (b/w) films. Panchromatic films are b/w films sensitive to the visible portion of the electromagnetic spectrum (0.4 to 0.7  $\mu\text{m}$ ). The sensitivity of black and white infrared films includes both the visible part of the spectrum and also the wavelengths 0.7 to 0.9  $\mu\text{m}$  (near infrared). It is important to note that infrared energy of these wavelengths does not represent heat emitted from objects, but simply reflected infrared energy to which the human eye is insensitive.

Color and color infrared films are also widely used for aerial photography. Although the cost of using these films is greater than for black and white films, they provide greater information content due to the human eye's ability to discriminate substantially more colors than shades of gray. Normal color films have three separate emulsion layers sensitive to blue, green, and red wavelengths, respectively. Color infrared films have three similar emulsion layers, but they are sensitive to green, red, and near-infrared wavelengths, respectively. Again, as in the case of b/w infrared films, it is reflected sunlight, not emitted energy, that is photographed with color infrared

film.

*Digital cameras* use a camera body and lens but record image data with charge-coupled devices (CCDs) rather than film. The electrical signals generated by these detectors are stored digitally, typically using media such as computer disks. Although this process is not "photography" in the traditional sense (images are not recorded directly onto photographic film), it is often referred to as "digital photography." Of course, hard copy photographs can also be converted into an array of digital picture elements (**pixels**) using some form of image scanner.

*Video cameras* are sometimes used as a substitute for small-format (70 mm and 35 mm) cameras. Video camera data are recorded on videotape, typically in HI-8 format.

The scale of photographs affects the level of useful information they contain. Small-scale photographs (1:50 000 or smaller) are used for reconnaissance mapping, large-area resource assessment, and large-area planning. Medium-scale photographs (1:12 000 to 1:50 000) are used for the identification, classification, and mapping of such items as tree species, agricultural crop types, vegetation communities, and soil types. Large-scale photographs (larger than 1:12 000) are used for the intensive monitoring of specific items such as surveys of the damage caused by plant diseases, insects, or tree blow-downs. Applications such as hazardous waste site assessment often require very-large-scale photographs.

The principles of **photogrammetry** can be used to obtain approximate distances and ground elevations from aerial photographs using relatively unsophisticated equipment and simple geometric concepts, as well as to obtain extremely precise maps and measurements using sophisticated "soft copy" instrumentation, digital images, and complex computational techniques.

## Multispectral, Thermal, and Hyperspectral Scanners

*Multispectral scanners* are electro-optical devices that sense selectively in multiple spectral bands using electronic detectors rather than film. They sense one small area on the ground at a time and, through scanning, build up two-dimensional images of the terrain for a swath beneath an aircraft or spacecraft. Through this process, they collect rows and columns of image data that can be computer processed. As shown in [Fig. 151.1](#), multispectral scanners can sense in a much broader spectral range than film. Multispectral scanners are the sensing devices used in the Landsat and SPOT satellites (discussed later).

*Thermal scanners* are electro-optical devices that sense in the thermal infrared portion of the electromagnetic spectrum. They do not record the true internal temperature of objects (kinetic temperature), but rather their apparent temperature based on the radiation from their top surfaces (radiant temperature). Because they sense energy emitted (rather than reflected) from objects, thermal scanning systems can operate day or night. Multiple thermal bands can be sensed simultaneously, as in the case of NASA's *Thermal Infrared Multispectral Scanner*. Successful interpretations of thermal imagery have been made in such diverse tasks as determining rock type and structure, locating geological faults, mapping soil type and moisture conditions, determining the thermal characteristics of volcanoes, studying evapotranspiration from vegetation, locating cold water springs, determining the extent and characteristics of thermal plumes in lakes and rivers, delineating the extent of active forest fires, and locating underground coal mine fires.

*Hyperspectral scanners* acquire multispectral images in many very narrow, contiguous spectral

bands throughout the visible, near-infrared, and mid-infrared portions of the electromagnetic spectrum. These systems typically collect 200 or more channels of data, which enables the construction of an effectively continuous reflectance spectrum for every pixel in the scene (as opposed to the 4–6 broad spectral bands used by the Landsat and SPOT satellites).

## Side-Looking Radar

An increasing amount of valuable environmental and resource information is being acquired by active radar systems that operate in the microwave portion of the spectrum. Microwaves are capable of penetrating the atmosphere under virtually all conditions. Depending on the specific wavelengths involved, microwave energy can penetrate clouds, fog, light rain, and smoke. Side-looking radar uses an antenna pointed to the side of the aircraft or spacecraft. Because the sensor is mounted on a moving platform, it is able to produce continuous strips of imagery depicting very large ground areas located adjacent to the flight line.

Microwave reflections from earth materials bear no direct relationship to their counterparts in the visible portion of the spectrum. For example, many surfaces that appear rough in the visible portion of the spectrum may appear smooth as seen by microwaves (e.g., a white sand beach). The appearance of various objects on radar images depends principally on the orientation of the terrain relative to the aircraft or spacecraft (important because this is a side-looking sensor), the object's surface roughness, its moisture content, and its metallic content.

Radar image interpretation has been successful in applications as varied as mapping major rock units and surficial materials, mapping geologic structure (folds, faults, and joints), discriminating vegetation types (natural vegetation and crops), determining sea ice type and condition, and mapping surface drainage patterns (streams and lakes).

## 151.4 Remote Sensing from Earth Orbit

---

The use of satellites as sensor platforms has made possible the acquisition of repetitive multispectral data of the earth's surface on a global basis. The principal earth resources satellites to date have been the U.S. Landsat and the French SPOT systems. The application of satellite image interpretation has already been demonstrated in many fields, such as agriculture, botany, cartography, civil engineering, environmental modeling and monitoring, forestry, geography, geology, geophysics, habitat assessment, land resource analysis, land use planning, oceanography, range management, and water resources.

The Landsat satellites image each spot on the earth's surface once each 16 days, providing for frequent, synoptic, repetitive, global coverage. The Landsat multispectral scanner currently in operation is the *Thematic Mapper*, which senses in six bands of the spectrum, from the blue through the mid-infrared, with a ground resolution cell size of 30 by 30 m. A seventh band senses in the thermal infrared with a ground resolution cell size of 120 by 120 m.

The SPOT satellites image each spot on the earth's surface once each 26 days, but the satellite can be aimed (using ground commands) as much as 27° from nadir to allow more frequent viewing opportunities (e.g., at a latitude of 45° a total of 11 viewing opportunities exist during each 26-day cycle). Stereoscopic imaging is also possible due to the off-nadir viewing capabilities. The

multispectral scanner of the current SPOT satellite senses in three bands of the spectrum (green, red, and near infrared) with a ground resolution cell size of 20 by 20 m. In its "panchromatic" (black and white) mode it senses in one broad band with a ground resolution cell size of 10 by 10 m.

The Canadian Radarsat satellite is planned for launch in 1995. This satellite will provide radar data with many possible swath widths and resolutions on a 1–3 day repeat coverage (depending on latitude). The primary applications for which Radarsat has been designed include ice reconnaissance, coastal surveillance, land cover mapping, and agricultural and forest monitoring.

Other earth resources satellites include those of the European Space Agency and the National Space Agency of Japan. Likewise, several other countries operate, or are planning to launch, earth resources satellites.

## 151.5 Digital Image Processing

---

The digital data acquired by multispectral and thermal scanners, radar systems, and digital cameras are typically computer processed to produce images through *digital image processing*. Through various image-processing techniques, digital images can be enhanced for viewing and human image interpretation. Digital data can also be processed using computer-based image classification techniques to prepare various thematic maps, such as land cover maps. Digital image-processing procedures are normally integrated with the functions of geographic information systems (GIS).

### Defining Terms

**Electromagnetic radiation:** The transmission of energy in the form of waves having both an electric and a magnetic component.

**Electromagnetic spectrum:** Electromagnetic radiation is most simply characterized by its frequency or wavelength. When electromagnetic waves are so ordered, the resulting array is called the *electromagnetic spectrum*. The spectrum is normally considered to be bounded by cosmic rays at the short wavelength end and by microwaves at the long wavelength end.

**Emitted energy:** The energy radiated by an object resulting from its internal molecular motion (heat). All objects above "absolute zero" in temperature radiate energy.

**Ground truth (or reference data):** Field observations or other information used to aid or verify the interpretation of remotely sensed data.

**Photogrammetry:** The science, art, and technology of obtaining reliable measurements, maps, digital elevation models, thematic GIS data, and other derived products from photographs.

**Pixel:** The cell representing each combination of row and column (picture element) in a digital data set.

**Reflected energy:** That component of incident energy that is reflected from an object.

**Remote sensing:** Studying the characteristics of objects from a distance by recording and analyzing electromagnetic energy, typically from ultraviolet to microwave wavelengths.

The Hubble Space Telescope was launched on April 24, 1990, with an optical flaw. In December 1993 after five days of extravehicular activity the telescope was successfully repaired. Additional servicing activities included the installation of new solar arrays that eliminate the jitter experienced as the telescope pans from day to night. This allows the telescope to point within 0.007 arcsec accuracy.

This photograph was taken on December 9, 1993, as the Hubble Space Telescope began its separation from the Space Shuttle *Endeavour* after it spent a week and a half berthed in the space vehicle's cargo bay. Part of the earth's horizon is visible in the upper right corner. (Photo courtesy of NASA.)

THIS SECTION PRESENTS THE BASIC CONCEPTS of control system theory and

examines the inherent structure of feedback control systems. Emphasis is given to basic techniques and methods for determining the transient behavior of systems. The chapters show how to design and modify systems to obtain the desired system performance.

The basic features of feedback control systems are explained and illustrated in **Chapter 152**. These features include improved stability and transient response, reduced sensitivity to parameter variations, better steady state accuracy, minimization of the effect of external disturbances, and the ability to automatically follow an input signal.

The transient response is governed by the location of the roots of the characteristic equation. **Chapter 153** shows how to plot the path of all the roots of the characteristic equation as the system gain  $K$  is varied. Thus, the value of  $K$  which yields the desired transient response is determined directly from the root-locus plot for the system.

Frequency response methods provide a different vantage point than transient response methods for viewing feedback control systems. **Chapter 154** introduces frequency response concepts and the determination of stability using the Nyquist stability criterion. The transfer function for a system may be determined experimentally by frequency response methods.

The correlation criteria which relate transient response to frequency response are explained in **Chapter 155**. Various system compensation techniques for changing the frequency response to achieve the desired transient behavior for the system are described. Finally, it is shown how the root-locus plot may be modified by various compensators to obtain good transient response.

**Chapter 156** addresses the application of control theory to the process industries. These industries typically involve continuous processes in industries such as chemical, petroleum, pulp and paper, steel, and electrical power generation. These processes tend to be highly nonlinear and difficult to model accurately. The complex and time-varying dynamics of such systems require all control designs to explicitly consider robustness to ensure stability and performance over the expected range of operating conditions.

With the advent of relatively inexpensive microcomputer systems, low-cost computer systems are now being incorporated into automotive and home appliance systems, for example. **Chapter 157** describes the basic procedures for designing such systems. Digital control systems are inherently more accurate and provide greater flexibility for controlling the transient response than analog systems.

The fundamental control problem in robotics is to determine the actuator signals required to ensure that the desired motion is executed in accordance with specified

performance criteria. Because a robot's dynamics are described by a set of coupled nonlinear differential equations, the solution may be quite complicated. As described in **Chapter 158**, the planning of the manipulator trajectory to achieve a desired motion is integrally linked to the control problem.

State variable feedback is used for the design of both nonlinear and linear control systems. However, to use state variable feedback, every state variable must be either measured or estimated. Since measuring every state variable is impractical for most control applications, a state estimator must be included. The design of state variable feedback systems is the topic of **Chapter 159**.

## Feedback

---

- 152.1 Characteristics of a Feedback Control System
- 152.2 Fundamentals of Feedback for Time-invariant Linear Systems
- 152.3 Illustrative Applications
- 152.4 Feedback in Nonlinear Systems
- 152.5 Summary of the Typical Steps in the Design of Feedback Systems

**William L. Brogan**

*University of Nevada, Las Vegas*

"Feedback, one of the most fundamental processes existing in nature, is present in almost all dynamic systems, including those within man, among men, and between men and machines" [DiStefano *et al.*, 1967]. The reflex action of the neural-muscular system when the hand touches a hot stove is one example. The corrections applied to an automobile steering wheel when the driver sees a deviation from the desired path is another. Performance reviews in the workplace or the classroom may lead to altered work assignments and either rewards or admonishments. The home furnace comes on whenever the thermostat-measured temperature falls sufficiently far below the desired temperature.

Each of these examples has a primary system or dynamic unit that produces an output, and a sensor or measurement unit that produces a feedback signal based upon that output. The input to the system depends on a comparison of the feedback signal with the goals for the system. The difference between a commanded input and the feedback signal is frequently used to drive the system. This error-correcting concept is the essence of feedback control. The history of feedback is summarized by Franklin *et al.* [1986], Dorf [1989], and D'Azzo and Houpis [1988].

### 152.1 Characteristics of a Feedback Control System

---

When applied properly, the effects of feedback are as follows:

1. Improved stability and transient response
2. Ability to automatically track a specified input
3. Higher steady state accuracy
4. Reduced sensitivity to parameter variations
5. Better disturbance rejection capability

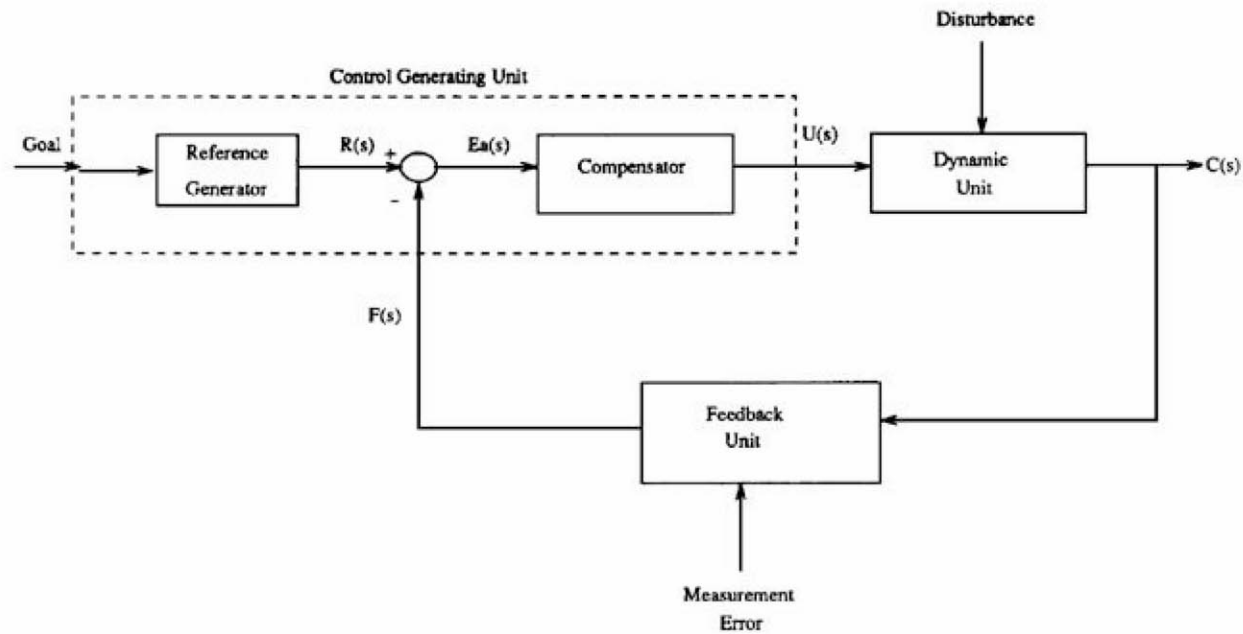

Feedback may bring certain disadvantages. Improperly applied feedback could cause instability. A loss of gain results from use of feedback and extra amplifier stages are needed. Additional high

precision components are required to provide the feedback signals.

## 152.2 Fundamentals of Feedback for Time-invariant Linear Systems

When all elements in the feedback loop of Fig. 152.1 can be described by linear, constant coefficient differential equations—Laplace transforms and transfer functions are convenient. This section deals with such systems. Digital or sampled data systems, described by difference equations, can be dealt with in similar ways using Z-transforms. When systems are high-order, time-variable, or nonlinear, the differential or difference equations must be dealt with directly, usually in state-variable format [Brogan, 1991].

**Figure 152.1** Block diagram of a generic feedback control system.

Let the forward loop transfer function from the **actuating signal** to the **dynamic unit** output be

$$C(s)/E_a(s) = KG(s) = Kg_n(s)/g_d(s) \quad (152.1)$$

where  $g_n(s)$  and  $g_d(s)$  are numerator and denominator polynomials. Let the transfer function of the feedback or **measurement unit** be

$$F(s)/C(s) = H(s) = h_n(s)/h_d(s) \quad (152.2)$$

The **open-loop** transfer function is defined as  $KG(s)H(s)$ . The actuating signal is  $E_a(s) = R(s) - F(s) = R(s) - H(s)C(s)$ . The term **error signal** will be reserved for the

difference between the input and the output:

$$E(s) = R(s) - C(s) \quad (152.3)$$

If  $H(s) = 1$ , then  $E(s) = E_a(s)$ . Using  $C(s) = KG(s)E_a(s)$ , algebraic manipulations give the **closed-loop** transfer functions from  $R(s)$  to  $C(s)$ ,  $E_a(s)$ , and  $E(s)$ , respectively, as

$$\begin{aligned} C(s)/R(s) &= KG(s)/[1 + KG(s)H(s)] \\ &= Kg_n(s)h_d(s)/[g_d(s)h_d(s) + Kg_n(s)h_n(s)] \end{aligned} \quad (152.4)$$

$$E_a(s)/R(s) = 1/[1 + KG(s)H(s)] \quad (152.5)$$

$$E(s)/R(s) = \{1 - KG(s)[1 - H(s)]\}/[1 + KG(s)H(s)] \quad (152.6)$$

External disturbances are ignored to this point. Knowledge of closed-loop pole locations allows prediction of stability, response time, and frequency of oscillation. Since Eqs. (152.4), (152.5), and (152.6) have the same denominators,  $c(t)$ ,  $e_a(t)$ , and  $e(t)$  all have the same types of terms in their time responses, as determined by the closed-loop poles, or roots of the characteristic equation

$$1 + KG(s)H(s) = 0 \quad \text{or} \quad g_d(s)h_d(s) + Kg_n(s)h_n(s) = 0 \quad (152.7)$$

The poles can be manipulated by choice of the gain  $K$ . This explains the ability of closed-loop systems to improve transient response compared with open-loop systems. Examples are provided later.

An open-loop system consisting of just the forward path  $KG(s)$  has the error

$$E(s) = R(s) - C(s) = [1 - KG(s)]R(s) \quad (152.8)$$

The equivalent closed-loop error is obtained from Eq. (152.6). The final value theorem of Laplace transforms allows evaluation of the steady state error value in either case. Traditionally, these errors are evaluated using step, ramp, and parabolic test input functions. The resulting errors are zero, finite, or infinite depending on the system type, that is, the number of poles of  $G(s)H(s)$  at the origin. From Eq. (152.8), an open-loop system will have a finite steady state error only if  $G(s)$  is type 0, and a zero error requires  $K = 1/G(0)$ . The feedback system steady state error is reduced by increasing the loop gain  $K$ , provided that all poles remain in the left-half plane. The position, velocity, and acceleration error constants (alternately step, ramp, and parabolic error coefficients) [D'Azzo and Houpis, 1988] are useful in evaluating these errors:

$$K_p = \lim_{s \rightarrow 0} [KG(s)H(s)] \quad (152.9)$$

$$K_v = \lim_{s \rightarrow 0} [sKG(s)H(s)] \quad (152.10)$$

$$K_a = \lim_{s \rightarrow 0} [s^2KG(s)H(s)] \quad (152.11)$$

The denominator in Eqs. (152.4), (152.5), and (152.6) is called the **return difference**  $R_d(s) = 1 + KG(s)H(s)$ . The return difference plays a major role in parameter sensitivity analysis. For example, sensitivity to perturbations in the forward transfer function  $G(s)$  is characterized by  $S_G = (\delta C/C)/(\delta G/G) = (\delta C/\delta G)(G/C)$ . For the open-loop system of Eq. (152.1)  $S_G = 1$ , meaning that the effect of a parameter error is reflected full strength into the output  $C(s)$ . The closed-loop system of Eq. (152.4) yields  $S_G = 1/R_d(s)$ . This sensitivity is reduced as the return difference is increased. The sensitivity to errors in  $H(s)$  is  $S_H = -KGH/(1 + KGH)$ . For high gain,  $S_H = -1$ , and  $C(s)/R(s) \rightarrow 1/H(s)$ . This means that performance depends almost exclusively on the feedback components. Using feedback with inaccurate components,  $H(s)$ , is not productive!

A feedback control system's ability to reduce the effect of external disturbances depends on the location where the disturbance enters the loop. Figure 152.2 shows a system with five separate disturbances. The return difference for this system is

$$R_d(s) = 1 + G_1(s)G_2(s)H_1(s)H_2(s) \quad (152.12)$$

For this linear system, superposition gives

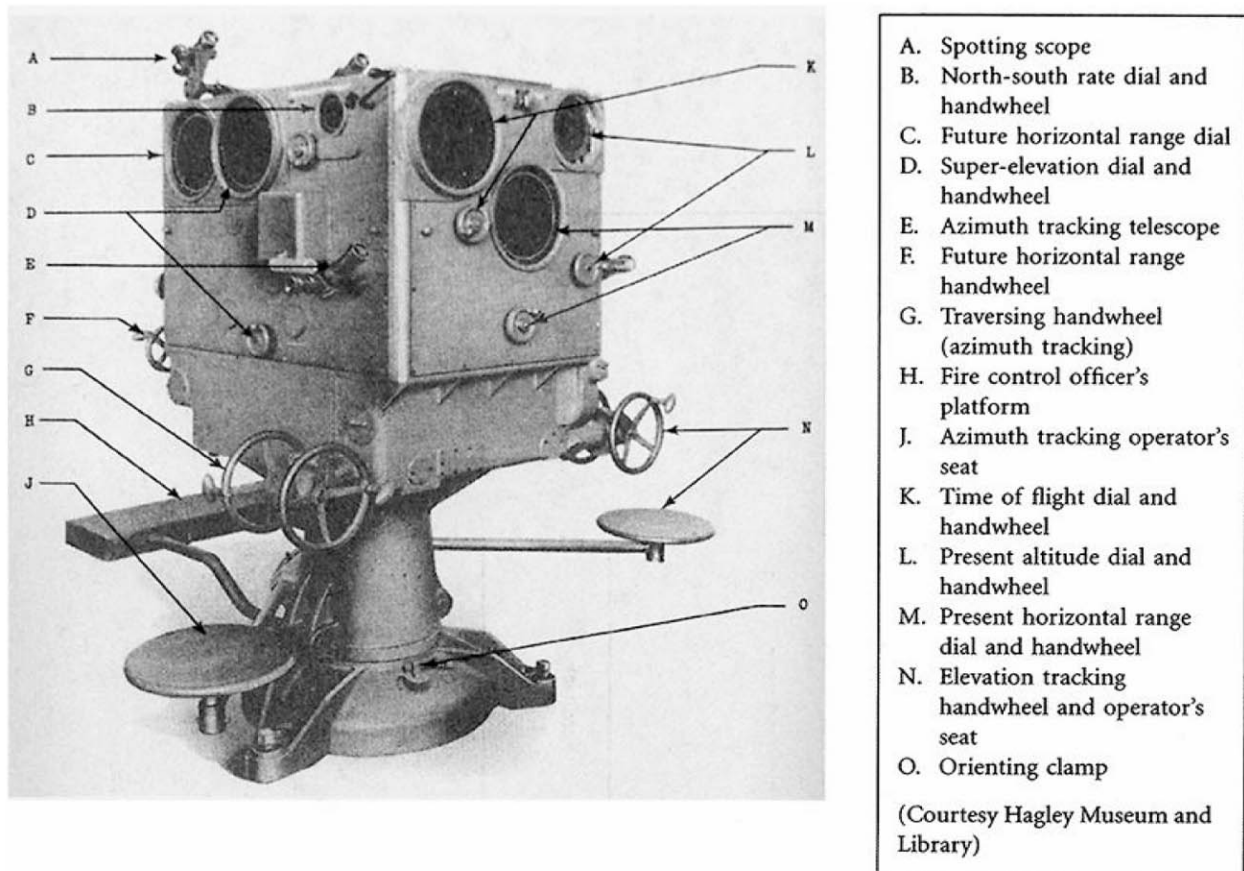

$$C(s) = [G_1G_2(R + D_1) + G_2D_2 + D_3 - H_1H_2G_1G_2D_4 - H_2G_1G_2D_5]/R_d(s) \quad (152.13)$$

When the return difference is much larger than unity,

$$C(s) \approx [R + D_1 + D_2/G_1 + D_3/(G_1G_2) - D_4H_1H_2 - D_5H_2]/(H_1H_2) \quad (152.14)$$

The desired output is caused by the reference input  $R$ . Contributions due to all disturbances  $D_i$  are undesirable. Since  $D_1$  enters the loop at the same point as  $R$ , nothing can be done with loop parameters to separate the two effects. The effect of  $D_2$  can be reduced if  $G_1$  has a high gain. The effect of  $D_3$  is reduced by increasing either  $G_1$  or  $G_2$ . Disturbance  $D_4$  has a smaller effect if  $H_1H_2$  is small. Finally,  $D_5$  effects are reduced if  $H_2$  is small. In all cases, the effect of a disturbance is reduced if the gain between the point of disturbance insertion and the output is small compared with the return difference. For a more complete look at disturbance rejection, see D'Azzo and Houpis [1988].

**Figure 1** The Sperry T-6 Director

## EARLY DISTRIBUTED CONTROL: ANTI-AIRCRAFT COMPUTERS AT SPERRY IN THE 1930S

### D. Mindell

*Massachusetts Institute of Technology*

From 1925 to 1940, the Sperry Gyroscope Company developed gun directors for controlling anti-aircraft guns. These devices were mechanical analog computers that connected four 3-inch anti-aircraft guns into an integrated system. Two tracking telescopes and a stereo rangefinder provide azimuth, elevation, and range data. The computer receives these data; incorporates manual adjustments for wind velocity, wind direction, muzzle velocity, air density, and other factors; and outputs three variables: azimuth, elevation, and a setting for the fuse. Manually set before loading, the fuse setting determines the time after firing at which the shell will explode (corresponding to slant range of the predicted position of the target). Shells are not intended to hit the target plane directly but rather to explode near it, scattering fragments to destroy it. The computer thus performs two main calculations: prediction and ballistics. Prediction corresponds to calculating the "lead" of the target, finding its position at some future time. Ballistic calculations correspond to looking up solutions in a "firing table," which determines the necessary gun elevation for a desired range. Here the firing table was mechanized by a "ballistic cam" or pin follower. The prediction and ballistics solution are coupled, since prediction requires a "time of flight" for the shell, which depends on the ballistics. A feedback loop thus connects the two calculations.

Figure 1 shows the Sperry T-6 director, built in 1930. A square box about four feet on a side, it was mounted on a pedestal on which it could rotate. The crew consisted of nine men. Three would sit on seats, and one or two would stand on a step mounted to the machine, revolving with the unit as the azimuth tracker followed the target. The remainder of the crew stood on a fixed platform; they would have had to shuffle around as the unit rotated. This was probably not a problem, as the rotation angles were small for any given engagement. The director's pedestal mounted on a trailer, on which data transmission cables and the rangefinder could be packed for transportation. Nearly all the work for the crew was in a "follow-the-pointer" mode: each man concentrated on an instrument with two indicating dials, one the actual and one the desired value for a particular parameter. With a hand crank he adjusted the parameter to match the two dials.

Even though the T-6 director took only three inputs, it still required nine operators. Mostly, these men connected one stage of the calculation to the next, "feeding back" data into the computer in a "follow-the-pointer mode." Later, many of these operators were replaced by servomechanisms, acting as impedance amplifiers to couple stages of the mechanical computer. But in the 1930s, servos could not perform this function as well as people. The data were noisy, and even an unskilled human eye could eliminate complications due to erroneous or corrupted data. Noisy data did more than corrupt firing solutions. The mechanisms themselves were rather delicate, and erroneous input data, especially if they indicated conditions that were not physically possible, could lock up or damage the mechanisms. The operators performed as integrators in both senses of the term: They integrated different elements into a system, and they integrated mathematically, acting as low-pass filters to reduce noise.

The Sperry directors of the 1930s were transitional, experimental systems. Exactly for that reason, however, they allow us to peer inside the process of automation, to examine the displacement of human operators by servomechanisms while the process was still under way. Sperry Company only gradually became comfortable with the automatic communication of data between subsystems. The company bragged about the low skill levels required of the operators of the machine, but in 1930 it was unwilling to remove them completely from the process. Men were the glue that held integrated systems together.

**Figure 2** The Sperry T-6 Director mounted on a trailer with operators. Note power supply at left and cables to other system elements. (Courtesy Hagley Museum and Library)

**Figure 152.2** Feedback system with multiple disturbances.

## 152.3 Illustrative Applications

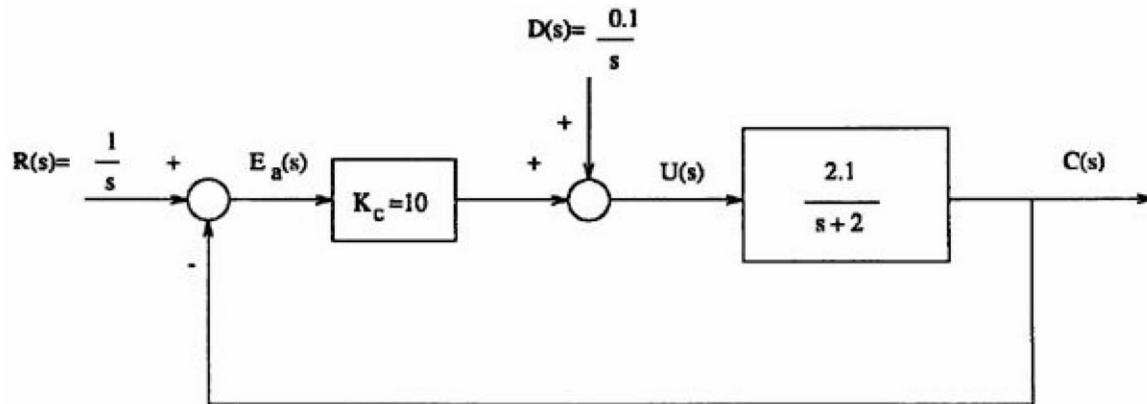

Two examples illustrate some major attributes of feedback. Suppose the speed of an automobile is ideally related to the depression of the throttle pedal by  $G(s) = 2/(s + 2)$ . A unit step input to an open-loop system leads to output  $c(t) = 1 - e^{-2t}$ . If the model is exact and no external disturbances exist, then open-loop control may suffice. However, assume that the numerator of  $G$  is actually 2.1 (a parameter error). Also, suppose that a 10% disturbance is acting so that  $R(s) + D(s) = 1.1/s$ . The open-loop response  $c(t) = 1.155(1 - e^{-2t})$  now has a 15.5% error. Figure 152.3 shows a feedback system (perhaps an automatic cruise control unit, or the driver responding to the speedometer) with the same parameter error and disturbance input. The control gain  $K_c = 10$  is arbitrarily chosen for illustration only. This type 0 system has  $K_p = 10.5$ . The steady state error (ignoring the disturbance) is  $e_{ss} = 1/(1 + K_p) = 0.08696$ . The closed-loop characteristic equation is  $(s + 23) = 0$ , indicating a much faster response. The actual output is  $c(t) = 0.92217(1 - e^{-23t})$ . The steady state error is  $-0.07783$ , roughly half the open-loop error. Figure 152.4 compares the open- and closed-loop responses. The plant input command also should be considered. In the open-loop configuration, it is a constant 1.1. In the closed-loop system, it is

$$u(t) = 0.878 + 9.22e^{-23t} \quad (152.15)$$

Initially, this is 9.18 times larger than the open-loop control signal, but smaller in steady state. This large initial spike causes the faster closed-loop response. Physical components may saturate, or in

other ways prevent, the achievement of performance predicted by linear mathematical models.

**Figure 152.3** Feedback system with parameter error and disturbance.

**Figure 152.4** Comparison of open- and closed-loop systems with disturbance and parameter error.

A second example is an unstable plant described by

$$G(s) = K/[(s - 1)(s + 2)(s + 5)] \quad (152.16)$$

With unity feedback system, Routh's criterion [Dorf, 1989] shows that this system is stable for  $10 < K < 28$ . The steady state error decreases with increasing  $K$  values in the stable range. For  $K = 10.2$  the output smoothly approaches a final value of 51, giving a steady state error of 50. As  $K$  increases, the rise time and steady state error decrease, but overshoot and oscillations increase. Simple adjustment of  $K$  cannot produce a satisfactory response. A rate feedback term  $K_r s$  is added next, giving  $H(s) = K_r s + 1$ . The value  $K_r = 0.5$  is selected arbitrarily to cancel the pole at  $s = -2$ . Routh's criterion now shows a stable system  $K > 10$ . Figure 152.5 compares output using proportional-plus-rate feedback with proportional feedback alone. Rate feedback has reduced response time and steady state error, eliminated the overshoot, and squelched the oscillations. If a total gain  $K = 500$  is divided between the plant with a factor 25 and the controller with a factor of 20, the input to the plant  $G(s)$  is

$$u(t) = -4.08 + e^{-2t} [20.4 \cos(15.5t) + 2.629 \sin(15.5t)] \quad (152.17)$$

This large amplitude oscillation might exceed the physical limits of the plant. This example shows that feeding back output derivatives, in addition to the output, provides stronger control over the process. Extensions of this idea lead to **state feedback**, a topic of Chapter 159. Also see Brogan [1991]. A treatment of compensator design is also presented in Chapter 155.

**Figure 152.5** Comparison of proportional feedback and proportional-plus-rate feedback.

## 152.4 Feedback in Nonlinear Systems

---

Few physical systems are truly linear over broad ranges of possible inputs. Many can be treated (approximately) as linear over a limited range. This is attractive because linear systems analysis methods are more fully developed. Feedback can cause some nonlinear open-loop systems to have linear closed-loop behavior. This is sometimes called dynamic linearization [Brogan, 1991]. Other systems are intentionally made nonlinear (e.g., by using on-off controllers) to improve performance. Adaptive and self-learning control systems use feedback and are inherently nonlinear. Feedback also plays an essential role in the training of artificial neural networks through back propagation, and in Kalman filtering and recursive least squares estimation. A predicted signal is compared with a measured signal. The difference is then used to adjust values of parameters or states to reduce future errors.

## 152.5 Summary of the Typical Steps in the Design of Feedback Systems

---

The development of a feedback system is often an iterative process. Typically the following sequence of questions must be addressed:

1. What are the goals for this system?
2. What are the appropriate measures of system performance in attempting to reach these goals?
3. Are there portions of the system that are fixed by other considerations? What are the mathematical models of these units?
4. How can the feedback system be easily analyzed in terms of the goals and performance measures?
5. How can the system be modified to improve performance?
6. What are the economic factors related to the product?

A certain degree of robustness can be provided by feedback. That is, precise feedback sensors add expense but can sometimes make up for deficiencies in a cheaper forward path plant and thus might lead to a lower total cost. Systematic methods of analysis and design of feedback systems are presented in **Chapters 153–159**.

### Defining Terms

**Actuating signal:** The difference between the reference input and the feedback signal.

**Closed-loop system:** System which contains one or more feedback signals that modify the input to the dynamic unit.

**Dynamic unit:** The principal plant or process being controlled.

**Error signal:** The difference between the reference input and the dynamic system's output.

**Measurement unit:** Device that produces the feedback signal.

**Open-loop system:** A system whose input is independent of its output.

**Poles:** Values of complex variable  $s$  that are roots of a transfer function denominator.

**Return difference:** The difference between a unit signal inserted at an "opened" point in a feedback system and the signal which returns around the loop to the other side of the break.

**Zeros:** Values of complex variable  $s$  that are roots of a transfer function numerator.

[153.1 The Root Locus Concept](#)[153.2 Root Locus Details](#)[153.3 Generation of Root Locus Plots](#)[153.4 Examples](#)[153.5 Summary and Conclusions](#)**William L. Brogan***University of Nevada, Las Vegas*

Evans [1950] introduced the root locus method of control systems analysis. The temporal behavior of a closed-loop system depends upon the location of the closed loop poles, or the roots of

$$1 + KG(s)H(s) = 0 \quad (153.1)$$

In a single loop control system,  $KG(s)$  is the forward path transfer function and  $H(s)$  is the feedback path transfer function. Multiple loop systems have more complicated characteristic equations that can be found using Mason's gain formula [D'Azzo and Houpis, 1988]. The closed-loop transfer function for a single loop feedback system is given in **Chapter 152** [Eq. (152.4)]. The denominator of that equation is the left side of Eq. (153.1). Root locus is a method for finding the  $n$  closed-loop poles [i.e., the roots of Eq. (153.1)] as the parameter  $K$  is varied. Partial fraction expansion and Laplace transform inversion give the control system time response, with one term due to each closed-loop pole. Major characteristics of the temporal behavior are determined solely by the pole locations. This explains the importance of root locus in control system design. Root locus procedures apply equally well to systems described by Z-transforms. The interpretation of root locations in the  $s$  and  $Z$  planes differ, but the process of plotting the roots is the same. This discussion is presented in terms of the Laplace  $s$  domain and is restricted to positive values of  $K$ .

## 153.1 The Root Locus Concept

---

Rearrangement of Eq. (153.1) gives  $KG(s)H(s) = -1$ , indicating that the complex number  $KG(s)H(s)$  must satisfy two conditions at any point  $s$  that is a root of Eq. (153.1):

The angle  $\phi$  must be an odd multiple of  $180^\circ$ ,  $\phi = \pm(2k + 1)180^\circ$ .

The magnitude  $|KG(s)H(s)|$  must be unity.

The root locus is the set of points in the complex plane that satisfies the angle condition. Let the numerator and denominator of  $KG(s)H(s)$  be of degrees  $m$  and  $n$ , respectively. Then, Eq. (153.1) has  $n$  roots, and the root locus has  $n$  branches. Evans developed a set of rules for sketching the paths that these  $n$  roots trace out as  $K$  is varied. Rough sketches are easy to draw and provide great insight into system behavior. The computer is used when complete and accurate plots are needed. Root locus uses the angle condition to find the root locations as functions of  $K$ . Then, the magnitude condition is used to find the gain  $K = 1/|G(s_1)H(s_1)|$  at a point  $s_1$  on the locus. Major root locus construction rules are now listed.

## 153.2 Root Locus Details

---

The numerator and denominator of the open-loop transfer function  $G(s)H(s)$  must be factored before the root locus method can be applied. The basis for root locus is the geometric interpretation of complex numbers represented as vectors. Let the numerator and denominator factors of  $G(s)H(s)$  be  $s + a_i$ , with the constants  $a_i$  either real or complex. Point  $s_1$  can be represented by the vector from the origin to  $s_1$ . The vector from  $-a_i$  to the origin is  $a_i$ . Addition gives  $s_1 + a_i$ , the vector from the pole or zero at  $-a_i$  to  $s_1$ . Each such vector is expressed in polar form, with magnitude  $\rho_i$  and angle  $\beta_i$ . The total angle of  $G(s_1)H(s_1)$  is the sum of  $\beta_i$  angles from the numerator terms, minus the  $\beta_i$  angles from the denominator terms. This total must equal  $(2k + 1)180^\circ$  (negative  $K$  would add  $180^\circ$  and require a change to some multiple of  $360^\circ$  to find the negative  $K$  locus). The angles can be measured with a protractor at a test point  $s_1$  and added.

The following rules simplify root locus plotting.

1. *Number of branches.* There are  $n$  branches of the root locus, where  $n$  is the number of open-loop poles  $G(s)H(s)$ .

2. *Loci starting points.* One branch of the positive gain root locus "begins" at each open-loop pole [poles of  $G(s)H(s)$ ]. These are the  $K = 0$  points.

3. *Locus behavior for large gain.* As  $K \rightarrow \infty$ , the product  $KGH$  must remain finite, which requires  $GH$  to be zero. This is true at the  $m$  open-loop zeros. As a result, as  $K \rightarrow \infty$ , one locus path approaches each of the  $m$  open-loop zeros. The remaining  $n - m$  paths go to  $\infty$ . When  $s$  is very large,  $KG(s)H(s) \rightarrow K/s^{n-m}$ .

4. *Asymptotic angles.* The angle condition at a test point  $s_1$  on an infinite circle shows that the angle to  $s_1$  must be  $\varphi_k = (2k + 1)180^\circ / (n - m)$  for some integer  $k$ .

5. *Loci ending points.* The  $K = \infty$  points are where the root loci branches "end." One branch of the root locus ends at each finite zero of  $G(s)H(s)$ . The remaining  $n - m$  branches go to infinity, with asymptotic angles  $\varphi_k$ .

6. *Centroid or center of gravity.* The vectors from the open-loop poles and zeros to an infinite point  $s_1$  on the locus appear to come from a common point  $\sigma$  on the real axis, called the centroid or center of gravity. Note that  $\sigma = \{\sum[\text{finite poles of } G(s)H(s)] - \sum[\text{finite zeros of } G(s)H(s)]\} / (n - m)$ . The  $n - m$  asymptotic rays emanating from the centroid  $\sigma$  are not part of the root locus. A root locus branch approaches each ray as  $K \rightarrow \infty$ .

7. *Real axis symmetry.* The root locus is mirror image symmetric with respect to the real axis because complex roots occur in conjugate pairs.

8. *Root loci on the real axis.* The angle condition shows that (for  $K \geq 0$ ) all sections of the real axis lying to the left of an odd number of open-loop poles or zeros are part of the root loci. There will be a closed-loop pole at each point in each such interval for some unique value of  $K$ . These real axis segments might be the composite of several nonoverlapping branches of the locus if breakaway points exist.

9. *Breakaway points of the root loci.* Breakaway points indicate multiple roots. The gain at such a point is called a critical gain. As  $K$  increases toward a critical value, two or more root paths converge or "break in" to the point from different directions. A further gain increase causes the multiple paths to "break away" from each other. The angle possibilities are given in Rule 11. At a critical  $s$ ,  $K$  has a relative maximum or minimum such that

$$d[G(s)H(s)]/ds = 0 \quad \text{or} \quad d[1/G(s)H(s)]/ds = 0.$$

The solution points can be either real (real axis break in or breakaway points) or complex (points where two branches intersect).

10. *Angles of arrival or departure for complex zeros or poles.* Consider a test point  $s_1$  on an infinitesimal circle centered at a complex open-loop pole or zero. Vectors from all other poles or zeros to this point have known angles. The angle criterion gives the angle of the infinitesimal vector from the complex pole or zero being tested. This is the arrival (zero) or departure angle (pole).

11. *Path angles at breakaway points.* If  $s_1$  is the location of a  $q$ th multiple root, then  $q$  branches of the locus break in at that point along paths uniformly spaced with angular separation  $360^\circ/q$ . As  $K$  increases beyond the critical value, the  $q$  branches break away along different paths also separated by  $360^\circ/q$ . [Figure 153.1](#) shows the only arrangements possible for real axis break in points with  $q = 2, 3$ , and  $4$ . One option in [Fig. 153.1](#) applies to the break in angles and the other (with reversal of the arrows) applies to the breakaway. A multiple open-loop pole is a special case ( $K = 0$ ) source of multiple paths. A multiple open-loop zero is a special case ( $K = \infty$ ) sink for multiple paths.

**Figure 153.1** Possible break in angles.

12. *Imaginary axis cross-over.* Routh's criterion [Dorf, 1989] can be used to find the  $j\omega$  axis locus cross-over points and the corresponding gain values.

13. *Conservation of sum of open- and closed-loop poles.* If  $n \geq m + 2$ , the sum of the closed-loop poles is constant for all  $K$  [D'Azzo and Houpis, 1988]. The sum is known from the open-loop poles.

## 153.3 Generation of Root Locus Plots

An approximate root locus plot can be sketched using just the easier-to-apply rules (1–8, 10, 11). A helpful analogy treats the fixed open-loop zeros as negatively charged particles and the closed-loop poles as positive charges. The attraction between unlike charges (repulsion between like charges) often helps visualize the shape of a root locus. An accurate root locus plot requires determination of break away and imaginary axis cross-over points (using Rules 9 and 12). Additional points must be found that satisfy the angle condition. This can be done by trial-and-error using a protractor or a spirule. This tedious effort is generally avoided by using a computer. Many root locus software packages exist, differing in the ease of use and quality of output.

## 153.4 Examples

Figure 153.2 gives the root locus for  $KG(s)H(s) = K/[s(s+3)]$ . This second order system has  $n = 2$  branches and  $m = 0$  zeros. Both branches approach  $\infty$  as  $K$  increases, along asymptotes at  $\pm 90^\circ$  from the centroid at the midpoint,  $s = -1.5$  (Rules 1–8). Rule 9 shows a break away point, also at  $s = -1.5$ , meaning that a double real root occurs there. The magnitude condition gives  $K = \rho_1 \rho_2 = 2.25$ . For  $K < 2.25$ , there are two unequal real roots between  $s = 0$  and  $-3$ . For  $K > 2.25$ , there are two complex conjugate roots. The angles at which the branches break away from the real axis are  $\pm 90^\circ$  (Rule 11). In this case, the complex loci coincide with the asymptotic angles. Rule 10 does not apply. Rule 12 finds no imaginary axis cross-overs. The sum of the roots is  $-3$  for all  $K$  (Rule 13).

**Figure 153.2** Stable second order system showing break away angles at double root.

An open-loop pole is added at  $s = -5$ , giving the root locus of Fig. 153.3. The new asymptotes are  $\pm 60^\circ$  and  $180^\circ$ , meaning that the third branch lying on the real axis to the left of  $s = -5$  goes to  $\infty$ . The other two asymptotes emanate from the centroid at  $s = -2.67$ . The charged particle analogy predicts that the added pole will push the breakaway point to the right of its former midpoint. The exact breakaway point can be found from Rule 9 ( $s = -1.207, K = 8.21$ ). The angles at which the loci leave the real axis are still  $\pm 90^\circ$ . Rule 12 gives the imaginary axis cross-over points ( $s = \pm j3.873, K = 120$ ). The closed-loop system will have damped oscillations for  $8.21 < K < 120$  and will be unstable for  $K > 120$ . From Rule 12, if two complex roots are selected with real parts at  $s = -1$ , the third root location will be at  $s = -6$  because the pole sum is  $-8$ . Placing a zero instead of a pole at  $s = -5$  gives the root locus in Fig. 153.4. The charged particle analogy predicts the attraction toward the zero will cause a leftward shift of the loci of Fig. 153.2. There are two loci branches. One terminates at the zero. The other goes to  $\infty$  along the negative real axis (Rules 3, 4, 5, and 8). Rule 9 gives multiple solutions:  $s = -1.838, K = 0.6754$  (breakaway point) and  $s = -8.162, K = 13.325$  (break in point). The system has complex poles (will oscillate) for  $0.6754 < K < 13.325$ , double real poles with  $K$  at either limit, and real distinct poles for all other positive  $K$ . The break away and break in angles are both  $\pm 90^\circ$ . The complex part of the loci is a circle centered at the zero (positive charges in orbit about a negative charge).

**Figure 153.3** Third order root locus, no finite zeros.

**Figure 153.4** Second order system with one zero. Double real roots for two different gains.

Adding a zero at  $s = -5$  and a pole at  $-8$  to the system of Fig. 153.2 gives the modified locus of Fig. 153.5. The asymptotes are  $\pm 90^\circ$ , with centroid at  $s = -3$ . The charged particle analogy correctly predicts a leftward deformation of the loci of Fig. 153.2. The zero at  $-5$  is closer and exerts stronger attraction than the repulsion exerted by the pole at  $-8$ . Rule 9 would give the exact breakaway point, but this requires factoring a cubic.

**Figure 153.5** Third order root locus, one finite zero.

**Figure 153.6** Conditionally stable third order system with complex zeros.

A system with  $KG(s)H(s) = K[s^2 + 2s + 4/3]/s^3$  is considered. The zeros are located at  $s = -1 \pm j/\sqrt{3}$ . There are  $n = 3$  paths, all starting at the triple pole at the origin and breaking away with angles  $\pm 60^\circ, 180^\circ$  (Rule 11). Rule 12 gives imaginary axis cross-overs at  $s = \pm 2j/\sqrt{3}$  with  $K = 2/3$ . One branch of the locus ends at each zero, and the angle of arrival (Rule 10) is  $180^\circ$ . The third branch goes to  $\infty$  along the negative real axis. This example illustrates a real axis break in and breakaway not at a pole or zero. Setting  $K = 6$  gives a triple root at  $s = -2$ . Rule 11, with knowledge that the real axis branch approaches from the right, shows that the break in angles are  $0^\circ$  and  $\pm 120^\circ$ . These paths continue and break away from the triple root point at angles  $180^\circ, \pm 60^\circ$ .

Figures 153.7, 153.8, and 153.9 illustrate root locus variations as the imaginary components of the complex open-loop poles are varied slightly. In each case, there are four branches, all ending at  $\infty$  along asymptotic angles  $\pm 45^\circ$  and  $\pm 135^\circ$  with a centroid at  $s = -1$ . The angle of departure from the positive complex pole is downward (i.e.,  $-90^\circ$ ). Figure 153.7 has a single break in point at  $s = -1$ , indicating a fourth order pole. The gain there,  $K = 1$ , is found by multiplying the four vector lengths to that point. Figure 153.1 provides angle information. The incoming angle choice is clear because two real axis branches approach the critical point. The outgoing paths coincide with the asymptotic rays. Similar considerations in Fig. 153.8 show a double real root at  $s = -1$  when  $K = 1.21$ , and a repeated pair of complex conjugate roots at  $s = -1 \pm 0.324j$  when  $K = 1.221$ .

Figure 153.9 indicates a double root at  $s = -1$  when  $K = 0.81$ . When  $K = 0.819$ , there are double roots at  $s = -0.69178$  and  $-1.30882$ .

**Figure 153.7** Fourth order system with potential fourth order root.

**Figure 153.8** Slightly modified system. Potential double complex roots.

**Figure 153.9** Modified system with three sets of potential double real roots.

## 153.5 Summary and Conclusions

Root locus design of feedback control systems reduces to (a) selecting closed-loop poles to give desired time response, (b) plotting the root locus, (c) finding the gain  $K$  if the desired poles are on the locus, and (d) reshaping the locus if it does not pass through the desired poles. This means adding suitable open-loop poles and zeros (compensation). Compensation is considered in

## Chapter 155.

### Defining Terms

**Angle condition:** Requirement that the phase angle be an odd multiple of  $180^\circ$ .

**Asymptotic angles:** Directions defining how loci approach infinity.

**Breakaway points:** Points where locus paths cross.

**Centroid:** Point from which the asymptotic angles are drawn.

**Magnitude condition:** The magnitude of  $K G(s) H(s)$  must be one.

**Poles:** Roots of the denominator of a transfer function.

Frequency response methods for the analysis and design of control systems were developed by H. Nyquist and H. W. Bode in the 1930s. These methods are older than, but not as intuitive as, the root locus, which was discovered by W. R. Evans in 1948. Frequency response yields a new vantage point from which to view feedback control systems. This technique possesses distinct advantages (1) when modeling transfer functions from physical data, (2) when designing lead compensators to meet a steady state error requirement and a transient response requirement, (3) when determining the stability of nonlinear systems, and (4) in settling ambiguities when sketching a root locus. This chapter introduces frequency response concepts and the determination of stability using the Nyquist criterion.

## 154.1 Concept and Definition of Frequency Response

---

In the steady state, sinusoidal inputs to a linear system generate sinusoidal responses of the same frequency. Even though these responses are of the same frequency as the input, they differ in amplitude and phase angle from the input. These differences are a function of frequency.

Sinusoids can be represented as complex numbers, or vectors, called **phasors**. The magnitude of the complex number is the amplitude of the sinusoid and the angle of the complex number is the phase angle of the sinusoid. Thus,  $M_1 \cos(\omega t + \phi_1)$  can be represented as  $M_1 \angle \phi_1$ , where the frequency,  $\omega$ , is implicit.

Since a system causes both the amplitude and phase angle of the input to be changed, we can

therefore think of the system itself represented by a complex number defined so that the product of the input phasor and the system function yields the phasor representation of the output.

Consider the system of Fig. 154.1 . Assume that the system is represented by the complex number,  $M(\omega)\angle\phi(\omega)$  . The output steady state sinusoid is found by multiplying the complex number representation of the input by the complex number representation of the system. Thus, the steady state output sinusoid is

$$M_o(\omega)\angle\phi_o(\omega) = M_i(\omega)M(\omega)\angle g(\phi_i(\omega) + \phi(\omega)) \quad (154.1)$$

From Eq. (154.1), we see that the system function is given by

$$M(\omega) = \frac{M_o(\omega)}{M_i(\omega)} \quad (154.2)$$

and

$$\phi(\omega) = \phi_o(\omega) - \phi_i(\omega) \quad (154.3)$$

Equations (154.2) and (154.3) form the definition of frequency response. We call  $M(\omega)$  the **magnitude frequency response**, and  $\phi(\omega)$  the **phase frequency response**. The combination of the magnitude and phase frequency responses is called the **frequency response** and is  $M(\omega)\angle\phi(\omega) = G(j\omega)$  .

**Figure 154.1** Steady state sinusoidal frequency response function.

If we know the transfer function,  $G(s)$  , of a system, we can find  $G(j\omega)$  by using the relationship [Nilsson, 1990]

$$G(j\omega) = G(s)|_{s \rightarrow +j\omega} = M(\omega)\angle\phi(\omega) \quad (154.4)$$

## 154.2 Plotting Frequency Response

$G(j\omega) = M(\omega)\angle\phi(\omega)$  can be plotted in several ways. Two of these ways are (1) as a function of frequency with separate magnitude and phase plots, or (2) as a polar plot, where the phasor length is the magnitude and the phasor angle is the phase. When plotting separate magnitude and phase plots, the magnitude curve can be plotted in decibels (dB) vs.  $\log \omega$ , where  $\text{dB} = 20 \log M$  . The phase curve is plotted as phase angle vs.  $\log \omega$  . Plots that use dB and log frequency are called **Bode plots** . Bode plots can be easily drawn using asymptotic approximations [Nise, 1995].

As an example, find the analytical expression for the frequency response of the system,  $G(s) = 1/(s + 2)$ . Then, plot the separate magnitude and phase diagrams, as well as the polar plot.

First, substitute  $s = j\omega$  in the system function and obtain  $G(j\omega) = 1/(j\omega + 2) = (2 - j\omega)/(\omega^2 + 4)$ . The magnitude of this complex function,  $|G(j\omega)| = M(\omega) = 1/\sqrt{\omega^2 + 4}$ , is the magnitude frequency response. The phase angle of  $G(j\omega)$ ,  $\phi(\omega) = -\tan^{-1}(\omega/2)$ , is the phase frequency response.

$G(j\omega)$  can be plotted in two ways—Bode plots and a polar plot. The Bode plots are shown in Fig. 154.2(a), where the magnitude diagram is  $20 \log M(\omega) = 20 \log (1/\sqrt{\omega^2 + 4})$  vs.  $\log \omega$ , and the phase diagram is  $\phi(\omega) = -\tan^{-1}(\omega/2)$  vs.  $\log \omega$ . The polar plot, shown in Fig. 154.2(b), is a plot of  $M(\omega) \angle \phi(\omega) = 1/\sqrt{\omega^2 + 4} \angle -\tan^{-1}(\omega/2)$  for different  $\omega$ .

**Figure 154.2** Frequency response plots for  $G(s) = 1/(s + 2)$ : (a) Bode plots, (b) polar plot.

## 154.3 Stability

A linear, time-invariant system is **stable** if the natural response approaches zero as time approaches infinity. A linear, time-invariant system is unstable if the natural response grows without bound as time approaches infinity. Finally, a linear, time-invariant system is marginally stable if the natural response neither decays nor grows, but remains constant or oscillates as time approaches infinity. From the point of view of the transfer function, stable systems have closed-loop transfer functions with only left half-plane **poles**, where a pole is defined as a value of  $s$  that causes  $F(s)$  to be infinite, such as a root of the denominator of a transfer function. Unstable systems have closed-loop transfer functions with at least one right half-plane pole and/or poles of multiplicity greater than one on the imaginary axis. Marginally stable systems have closed-loop transfer functions with only imaginary axis poles of multiplicity one and left half-plane poles. Stability is the most important system specification. An unstable system cannot be designed for a specific transient response or steady state error requirement. Physically, instability can cause damage to a system, adjacent property, and human life. Many times, systems are designed with limit stops to prevent total runaway.

### CONTROL SYSTEMS AND THE NATIONAL DEFENSE RESEARCH COMMITTEE

*D. Mindell,*

*Massachusetts Institute of Technology*

With war approaching in 1940, Vannevar Bush, former MIT professor of electrical engineering and President of the Carnegie Institute of Washington, persuaded President Roosevelt to establish the National Defense Research Committee (NDRC) to bring the nation's scientific talent to bear on military problems. The NDRC and its successor and umbrella organization, the Office of Scientific Research and Development (OSRD), would become among the most successful wartime agencies, spending over \$500 million on scientific research during the war. They supervised work on the atomic bomb (which moved to the Army when it became the Manhattan Project), the development of microwave radar (at MIT's radiation lab), applications of penicillin, proximity fuses, operations research, and a host of other technologies that define our modern world.

In the field of control systems, the NDRC took prewar feedback and regulation techniques and transformed them into modern control engineering. The Fire Control Division of the NDRC, under the leadership of mathematician Warren Weaver and then under servo pioneer Harold Hazen, supervised a broad array of research into building automatic machines to shoot down attacking aircraft. A contract with the NDRC founded the MIT Servomechanisms Laboratory, which, under the leadership of Gordon Brown and Jay Forrester, would go on to build Whirlwind, the first digital computer for real-time control. Students of Brown, including Herbert Harriss and A. C. Hall, also began to combine the time-domain "transient analysis" developed for servomechanisms with the frequency-oriented Nyquist techniques developed for electronic amplifiers. The NDRC also funded Norbert Wiener, whose wartime work in antiaircraft control led to his famous 1948 book *Cybernetics*. Claude Shannon, founder of information theory, also worked on fire control.

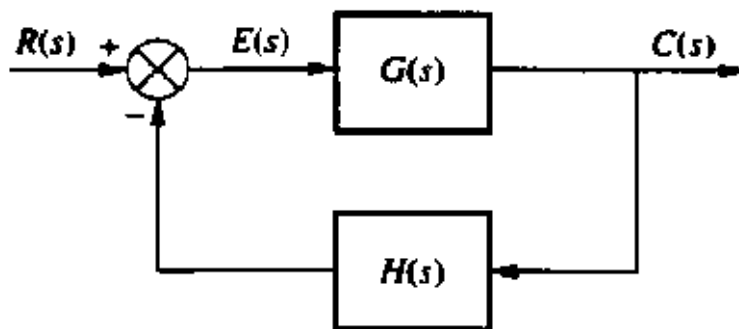

Along with H. Bode and R. C. Blackman at Bell Labs, Shannon studied noise in control systems as a problem in communications engineering, "since data smoothing is evidently a special case of the transmission, manipulation, and utilization of intelligence," thus sowing the seeds for information theory. Harold Hazen directed the NDRC to fund a broad program of "human factors" research, combining engineers and psychologists to understand the human dimension of control systems design. The Moore School of Electrical Engineering, under NDRC fire control contracts, did research in computing ballistics solutions for antiaircraft guns. When this group proposed their idea for an electronic numeric integrator and calculator, however, the NDRC turned it down as not being of immediate application to the war. Under a separate Army contract, this idea became ENIAC, the first electronic digital computer.

The NDRC project which achieved greatest success in the field prefigured the "cybernetic battlefield," so much a part of modern warfare. An electronic gun director developed by Bell Labs (the M-9) was integrated and combined with an automatic tracking radar built by the Radiation Lab (the SCR-584), electrohydraulic power controls built by Sperry, and the proximity fuse built by Johns Hopkins Applied Physics Laboratory. Together, this equipment formed the first automatic antiaircraft fire control system, precursor of Nike, ABM, and Patriot. It proved especially good at shooting down V-1 "buzz bombs" which attacked London in the summer of 1944. The straight and level flight path of the early cruise missiles made them particularly vulnerable to "straight-line" prediction methods employed by the Bell Labs computer. From July 18 to August 31, 1944, the system shot down 1286 V-1s, or 34% of the total attack. The servo engineering done at the Radiation Lab for the NDRC on the project, which coupled "conical scanning" radar to a servo-controlled antenna, led to the 1947 book by James, Nichols, and Phillips, *Theory of Servomechanisms*, which became the standard textbook in control theory after the war.

## 154.4 Nyquist Criterion for Stability

The **Nyquist criterion** relates the stability of a closed-loop system to the open-loop frequency response and open-loop pole location. Consider the system of [Fig. 154.3](#). The Nyquist criterion can tell us how many closed-loop poles are in the right half-plane.

**Figure 154.3** Closed-loop control system.

Before stating the Nyquist criterion, let us discuss the concept of *mapping*. If we take a complex number on the  $s$  plane and substitute it into a function,  $F(s)$ , another complex number will result. This process is called mapping. For example, substituting  $s = 4 + j3$  into the function  $(s^2 + 2s + 1)$  yields  $16 + j30$ . We say that  $4 + j3$  maps into  $16 + j30$  through the function  $(s^2 + 2s + 1)$ .

Now consider a collection of points, called a *contour*, shown in Fig. 154.4 as contour A. Also, assume

$$F(s) = \frac{(s - z_1)(s - z_2) \dots}{(s - p_1)(s - p_2) \dots} \quad (154.5)$$

**Figure 154.4** Mapping contour A through function  $F(s)$  to contour B.

Contour A can be mapped through  $F(s)$  into contour B by substituting each point of contour A into the function  $F(s)$  and plotting the resulting complex numbers. For example, point P in Fig. 154.4 maps into point Q through the function  $F(s)$ . Let us now put these concepts together and state the Nyquist criterion for stability [see (Nise,1995) for derivation]:

Assume the system of Fig. 154.3, where the open-loop transfer function is  $G(s)H(s)$  and the closed-loop transfer function is  $T(s) = G(s)/[1 + G(s)H(s)]$ . If a contour A that encircles the entire right half-plane, as shown in Fig. 154.5, is mapped through  $G(s)H(s)$  into contour B, then  $Z = P - N$ . Z is the number of closed-loop poles [the poles of  $T(s)$ ] in the right half-plane, P is the number of open-loop poles [the poles of  $G(s)H(s)$ ] in the right half-plane, and N is the number of counterclockwise encirclements of  $-1$  of contour B. The mapping, contour B, is called the **Nyquist diagram**.

The Nyquist criterion is classified as a frequency response technique because, around contour A in Fig. 154.5, the mapping of the points on the  $j\omega$  axis through the function  $G(s)H(s)$  is the same as substituting  $s = j\omega$  into  $G(s)H(s)$  forming the frequency response function,  $G(j\omega)H(j\omega)$ . Thus, part of the Nyquist diagram is the polar plot of the frequency response of  $G(s)H(s)$ . Let us look at two examples that illustrate the application of the Nyquist criterion.

In Fig. 154.6(a), contour A maps through  $G(s)H(s)$  into a Nyquist diagram that does not encircle  $-1$ . Hence,  $P = 0$ ,  $N = 0$ , and  $Z = P - N = 0$ . Because  $Z = 0$  is the number of closed-loop poles inside contour A, which encircles the right half-plane, this system does not have any right half-plane poles and is stable.

**Figure 154.5** Contour enclosing right half-plane to determine stability.

**Figure 154.6** Examples of mapping for the Nyquist criterion: (a) contour A does not enclose closed-loop poles; (b) contour A encloses closed-loop poles.

○ = zeros of  $1 + G(s)H(s)$   
 = poles of closed-loop system  
 Location not known

× = poles of  $1 + G(s)H(s)$   
 = poles of  $G(s)H(s)$   
 Location is known

On the other hand, Fig. 154.6(b) shows a contour  $A$  that generates two clockwise encirclements of  $-1$  when mapped through the function  $G(s)H(s)$ . Thus,  $P = 0$ ,  $N = -2$ , and  $Z = P - N = 2$ . The system is unstable because it has two closed-loop poles in the right half-plane ( $Z = 2$ ). The two closed-loop poles are shown inside contour  $A$  in Fig. 154.6(b) as zeros of  $1 + G(s)H(s)$ . The reader should keep in mind that the existence of these poles is not known a priori.

In this example, notice that clockwise encirclements imply a negative value for  $N$ . The number of encirclements can be determined by drawing a test radius from  $-1$  in any convenient direction and counting the number of times the Nyquist diagram crosses the test radius. Counterclockwise crossings are positive and clockwise crossings are negative. For example, in Fig. 154.6(b), contour  $B$  crosses the test radius twice in a clockwise direction. Hence, there are  $-2$  encirclements of the point  $-1$ .

## 154.5 Gain Design for Stability via the Nyquist Criterion

We now use the Nyquist criterion to design a system's gain for stability. The general approach is to set the loop gain equal to unity and draw the Nyquist diagram. Since gain is simply a multiplying factor, the effect of the gain is to multiply the resultant by a constant anywhere along the Nyquist diagram. For example, consider Fig. 154.7, which summarizes the Nyquist approach for a system with variable gain  $K$ . As the gain is varied, we can visualize the Nyquist diagram [Fig. 154.7(c)] expanding (increased gain) or shrinking (decreased gain) like a balloon. This motion could move the Nyquist diagram past the  $-1$  point and change the stability picture. For this system, since  $P = 2$ , the critical point must be encircled two times in the counterclockwise direction by the Nyquist diagram to yield  $N = 2$  and a stable system. A reduction in gain would place the critical point outside the Nyquist diagram where  $N = 0$  yielding  $Z = 2$ , an unstable system.

**Figure 154.7** Feedback control system to demonstrate Nyquist stability: (a) system, (b) contour, (c) Nyquist diagram.

From another perspective, we can think of the Nyquist diagram as remaining stationary and the  $-1$  point moving along the real axis. In order to do this, we set the gain to unity and position the critical point at  $-1/K$  rather than  $-1$ . Thus, the critical point appears to move closer to the origin as  $K$  increases.

Finally, if the Nyquist diagram intersects the real axis at  $-1$ , then  $G(j\omega)H(j\omega) = -1$ . From the root locus, when  $G(s)H(s) = -1$ , the variable  $s$  is a closed-loop pole of the system. Thus, the frequency at which the Nyquist diagram intersects  $-1$  is the same frequency at which the root locus crosses the  $j\omega$  axis. Hence, the system is marginally stable if the Nyquist diagram intersects the real axis at  $-1$ .

In summary, if the open-loop system contains a variable gain  $K$ , set  $K = 1$  and sketch the Nyquist diagram. Consider the critical point to be at  $-1/K$  rather than at  $-1$ . Adjust the value of gain  $K$  to yield stability based upon the Nyquist criterion.

Let us look at an example. For a unity feedback system, where  $G(s) = K/[s(s+3)(s+5)]$ , find the range of gain  $K$  for stability, instability, and marginal stability. For marginal stability, also find the frequency of oscillation.

First, set  $K = 1$  and sketch the Nyquist diagram for the system using the contour shown in Fig. 154.8(a). Conceptually, the Nyquist diagram is plotted by substituting the points of the contour shown in Fig. 154.8(a) into  $G(s) = 1/[s(s+3)(s+5)]$ . The contour, as shown, must detour around open-loop imaginary axis poles in order to plot a continuous Nyquist diagram. The detour, however, is epsilon close to the open-loop poles to ensure that any closed-loop right half-plane poles close to the imaginary open-loop poles are still inside the contour and are counted.

**Figure 154.8** (a) Contour for example; (b) Nyquist diagram.

From A to B, we use

$$G(j\omega) = \frac{1}{s(s+3)(s+5)} g|_{s \rightarrow j\omega} = \frac{-8\omega^2 - j\omega(15 - \omega^2)}{64\omega^4 + \omega^2(15 - \omega^2)^2} \quad (154.6)$$

and let  $\omega$  vary from  $0+$  to  $\infty$ . The mapping in Fig. 154.8(b) goes from A' at  $\infty$  to B' at the origin.

Around the infinite circle from B through C to D, the mapping is found by replacing each complex factor in  $G(s)$  by its polar form. Thus,

$$G(s) = \frac{1}{(R_0 \angle \theta_0)(R_3 \angle \theta_3)(R_5 \angle \theta_5)} \quad (154.7)$$

The angles are the angles drawn from the respective poles to a point on the infinite circle. The  $R_i$ s are the vector lengths (in this case, infinite). Hence, all points on the infinite circle map into the origin.

The negative imaginary axis from  $D$  to  $E$  maps into a mirror image of the mapping from  $A$  to  $B$ , because  $G(j\omega)$  has an even real part and an odd imaginary part.

From  $E$  through  $F$  to  $A$ , we can again use Eq. (154.7).  $R_0$  is zero. Thus, the resultant magnitude is infinite. At  $E$ , the angles add to  $-90^\circ$ . Hence, the resultant is  $+90^\circ$ . Similar reasoning yields the mapping of  $F$  and  $A$  to  $F'$  and  $A'$ , respectively.

Finally, let us find the point where the Nyquist diagram intersects the negative real axis. We set the imaginary part of Eq. (154.6) equal to zero using  $\omega = \sqrt{15}$ . Then we substitute this value of  $\omega$  back into Eq. (154.6) and find that the real part equals  $-0.0083$ .

From the contour of Fig. 154.8(a),  $P = 0$  and, for stability,  $N$  then must be equal to zero. From Fig. 154.8(b), the system is stable if the critical point lies outside the contour ( $N = 0$ ) so that  $Z = P - N = 0$ . Thus,  $K$  can be increased by  $1/0.0083 = 120.48$  before the Nyquist diagram encircles  $-1$ . Hence, for stability,  $K < 120.48$ . For marginal stability,  $K = 120.48$ . At this gain, the Nyquist diagram intersects  $-1$ , and the frequency of oscillation is  $\sqrt{15}$  rad/s.

Now that we have used the Nyquist diagram to determine stability, we can develop a simplified approach that uses only the mapping of the positive  $j\omega$  axis.

## 154.6 Stability via Separate Magnitude and Phase Plots(Bode Plots)

In many cases, stability can be determined from just a mapping of the positive  $j\omega$  axis, or, in other words, stability can be determined from the frequency response of the open-loop transfer function. Consider a stable open-loop system, such as that shown in Fig. 154.6(a). Since the open-loop system does not have right half-plane poles,  $P = 0$ . For the closed-loop system to be stable,  $N = 0$  yields  $Z = P - N = 0$ .  $N = 0$  (i.e., no encirclements of  $-1$ ) implies that the Nyquist diagram passes to the right of  $-1$ . Stated another way, the gain of the open-loop transfer function is less than unity at  $180^\circ$ . Thus, if we use Bode plots, we can determine stability from the open-loop frequency response by looking at the magnitude response curve where the phase is  $180^\circ$ . If the gain is less than unity at this frequency, the closed-loop system is stable.

Let us look at an example and determine the range of gain for stability of a system by implementing the Nyquist stability criterion using asymptotic log-magnitude and phase plots. From the log-magnitude plot, we will determine the value of gain that ensures that the magnitude is less than 0 dB (unity gain) at the frequency where the phase is  $\pm 180^\circ$ .

Shown in Fig. 154.9 are the asymptotic approximations to the frequency response of  $G(s) = K/[(s+2)(s+4)(s+5)]$ , scaled to  $K = 40$ . Since this system has all of its open-loop poles in the left half-plane, the open-loop system is stable. Hence, the closed-loop system will be stable if the open-loop frequency response has a gain less than unity when the phase is  $180^\circ$ . Accordingly, we see that at a frequency of approximately 7 rad/s, when the phase plot is  $180^\circ$ , the magnitude plot is  $-20$  dB. Therefore, an increase in gain of  $+20$  dB is possible before the system becomes unstable. Since the gain plot was scaled for a gain of 40,  $+20$  dB (a gain of 10) represents the required increase in gain above 40. Hence, the gain for instability is  $40 \times 10 = 400$ . The final result is  $0 < K < 400$  for stability. This result, obtained by approximating the frequency response by Bode asymptotes, can be compared to the result obtained from the actual frequency response, which yields a gain of 378 at a frequency of 6.16 rad/s.

**Figure 154.9** Log-magnitude and phase plots.

In this chapter, we discussed the concept of frequency response, including the Nyquist criterion and its application to the stability of linear feedback control systems. The concept of frequency response can be further applied to transient response analysis and design. Frequency response techniques can also be applied to digital and nonlinear control systems.

## Defining Terms

**Code plot:** A sinusoidal frequency response plot where the magnitude response is plotted separately from the phase response. The magnitude plot is decibels vs. log frequency, and the phase plot is phase vs. log frequency. In control systems, the Bode plot is usually made for the open-loop transfer function.

**Frequency response:** The combination of magnitude and phase frequency responses expressed as separate magnitude and phase responses, or as a complex function of frequency.

**Magnitude frequency response:** The ratio of the magnitude of the steady state sinusoidal response to the magnitude of the sinusoidal input as a function of frequency. The ratio can be expressed in dB.

**Nyquist criterion for stability:** Assume a feedback system where the open-loop transfer function is  $G(s)H(s)$  and the closed-loop transfer function is  $T(s) = G(s)/[1 + G(s)H(s)]$ . If a contour  $A$  that encircles the entire right half-plane is mapped through  $G(s)H(s)$  into contour

$B$ , then  $Z = P - N$ .  $Z$  is the number of closed-loop poles [the poles of  $T(s)$ ] in the right half-plane,  $P$  is the number of open-loop poles [the poles of  $G(s)H(s)$ ] in the right half-plane, and  $N$  is the number of counterclockwise encirclements of  $-1$  of contour  $B$ . The mapping, contour  $B$ , is called the Nyquist diagram.

**Nyquist diagram:** A mapping of a closed-contour on the  $s$  plane that encloses the right half-plane.

**Phase frequency response:** The difference between the phase angle of the steady state sinusoidal response and the phase angle of the input sinusoid as a function of frequency.

**Phasor:** A complex number, or vector, representing a sinusoid.

**Pole:** A value of  $s$  that causes  $F(s)$  to be infinite, such as a root of the denominator of a transfer function.

**Stability of a linear, time-invariant system:** That characteristic of a linear, time-invariant system defined by a natural response that decays to zero as time approaches infinity.

The frequency response of a control system may be determined experimentally. Since this is the frequency response for the actual system, correlation criteria which relate transient response to frequency response may then be used to ascertain the transient behavior of the system. Various system **compensation** techniques are available for changing the frequency response so as to improve the transient behavior of the system.

## 155.1 Correlation between Transient and Frequency Response

Figure 155.1 shows a second order, type 1 system. For this system, the **natural frequency** is  $\omega_n = \sqrt{K_1/\tau}$  and the **damping ratio** is  $\zeta = 1/(2\sqrt{K_1\tau})$ . The transient behavior is completely described by  $\zeta$  and  $\omega_n$  [Raven, 1995]. For a sinusoidal input  $r(t) = r_o \sin \omega t$ , after the initial transients have died out, the response will be  $c(t) = c_o \sin(\omega t + \phi)$ . The ratio of the amplitude of the output sinusoidal  $c_o$  to the input sinusoidal  $r_o$  is  $M = c_o/r_o$ . The value of  $\omega$  at which  $M$  is a maximum is

$$\omega_p = \omega_n \sqrt{1 - \zeta^2} \quad 0 \leq \zeta \leq 0.707 \quad (155.1)$$

where  $\omega_p$  is the value of  $\omega$  at which  $M$  attains its peak or maximum value. The corresponding peak or maximum value of  $M$  which is designated  $M_p$  is

$$M_p = \frac{1}{2\zeta\sqrt{1 - \zeta^2}} \quad 0 \leq \zeta \leq 0.707 \quad (155.2)$$

The preceding result has significance only for  $0 \leq \zeta \leq 0.707$  , in which case  $M_p \geq 1$  . Solving Eq. (155.2) for the damping ratio  $\zeta$  gives

$$\zeta = [(1 - \sqrt{1 - 1/M_p^2}) / 2]^{1/2} \quad M_p \geq 1 \quad (155.3)$$

The transient behavior of higher order, type 1 systems is closely approximated by the preceding correlation criteria. For the case in which  $M_p < 1$  , the transient response is described by a first order, type 1 system whose time constant  $\tau_c$  is

$$\tau_c = 1/\omega_c \quad M_p < 1 \quad (155.4)$$

where  $\omega_c$  is the value of  $\omega$  at which the  $G(j\omega)H(j\omega)$  plot crosses the unit circle. That is,  $|G(j\omega)H(j\omega)| = 1$  .

**Figure 155.1** Second order, type 1 system.

Figure 155.2 shows a second order, type 0 system. For this system, the natural frequency is  $\omega_n = \sqrt{(1 + K_o)/b}$  , and the damping ratio is  $\zeta = a/(2\sqrt{(1 + K_o)b})$  . The value of  $\omega$  at which  $M$  is a maximum is the same as that given by Eq. (155.1). The corresponding peak or maximum value of  $M$  is

$$\frac{M_p}{K_o/(1 + K_o)} = \frac{1}{2\zeta\sqrt{1 - \zeta^2}} \quad 0 \leq \zeta \leq 0.707 \quad (155.5)$$

For large values of  $K_o$  , then  $K_o/(1 + K_o) \approx 1$  , and this criterion becomes the same as that for a type 1 system. Solving Eq. (155.5) for the damping ratio  $\zeta$  gives

$$\zeta = \{ [1 - \sqrt{1 - (K/M_p)^2}] / 2 \}^{1/2} \quad M_p/K \geq 1 \quad (155.6)$$

where

$$K = K_o/(1 + K_o)$$

For the case in which  $M_p/K = M_p/[K_o/(1 + K_o)] < 1$  , the transient response is described by a first order, type 0 system whose time constant  $\tau_c$  is

$$\tau_c = 1/\omega_c \quad (155.7)$$

where  $\omega_c$  is the value of  $\omega$  at which the  $G(j\omega)H(j\omega)$  plot crosses the circle whose radius is

$$r = \frac{K_o}{\sqrt{1 + (1 + K_o)^2}} \quad (155.8)$$

For large values of  $K_o$ , the radius  $r$  approaches the unit circle and the preceding criterion becomes the same as that for a type 1 system.

**Figure 155.2** Second order, type 0 system.

## 155.2 Determining $K$ to Yield a Desired $M_p$

Figure 155.3 shows a typical polar plot of  $G(j\omega)H(j\omega)$ . If the gain  $K$  of the system is doubled, the value  $G(j\omega)H(j\omega)$  is doubled at every point. Multiplying the old scale by a factor of 2 yields the polar plot for the system in which the gain  $K$  has been doubled. Values of this new scale are shown in parentheses. Changing the gain  $K$  does not affect the shape of the polar plot.

**Figure 155.3** Typical polar plot.

An  $M$  circle is shown in Fig. 155.4. The center of the circle is located on the real axis at  $-M^2/(M^2 - 1)$ , and the radius is  $M/(M^2 - 1)$ . The line drawn from the origin, tangent to the  $M$  circle at the point  $P$ , has an included angle of  $\psi$ . The value of  $\sin \psi$  is

$$\sin \psi = 1/M \quad (155.9)$$

**Figure 155.4** Tangent to an  $M$  circle.

A characteristic feature of the point of tangency  $P$  is that a line drawn from the point  $P$  perpendicular to the negative axis intersects this axis at the  $-1$  point.

The procedure for determining the gain  $K$  so that the  $G(j\omega)H(j\omega)$  plot will have a desired value of  $M_p$  is as follows.

1. Draw the polar plot for  $G(j\omega)H(j\omega)/K$ .
2. Draw the tangent line to the desired  $M_p$  circle [ $\psi = \sin^{-1}(1/M_p)$ ].
3. Draw the circle with center on the negative real axis that is tangent to both the  $G(j\omega)H(j\omega)/K$  plot and the tangent line, as is shown in Fig. 155.5.
4. Erect the perpendicular to the negative real axis from point  $P$ . This perpendicular intersects the negative real axis at the point  $-A = -0.05$ .

5. In order that the circle drawn in step 3 is the desired  $M_p$  circle, this point should be  $-1$  rather than  $-A$ . The required gain is that value of  $K$  which changes the scale so that this does become the  $-1$  point. Thus  $K(-A) = -1$  or  $K = 1/A$ .

**Figure 155.5** Determination of  $K$  to yield a desired  $M_p$ .

As is illustrated in Fig. 155.5, the perpendicular drawn from point  $P$  to the negative real axis intersects the axis at the value  $-A = -0.05$ . Multiplication of the scale by a factor of 20, as is shown in Fig. 155.5 by the numbers in parentheses, converts this point to the  $-1$  point. Thus, the required value of the gain  $K$  such that the polar plot  $G(j\omega)H(j\omega)$  is tangent to the desired  $M_p$  circle is 20.

The plot  $G(j\omega)H(j\omega)/K$  is the plot for the case in which  $K$  is one. By constructing the plot for  $G(j\omega)H(j\omega)$  rather than  $G(j\omega)H(j\omega)/K$ , the resulting value of  $1/A$  represents the required factor  $K_c$  by which the gain should be changed such that the resulting polar plot will be tangent to the desired  $M_p$  circle. That is,

$$\text{New gain} = K_c (\text{original gain}) \quad (155.10)$$

Another method for representing frequency response information is the log-modulus or Nichols plot [Nichols, 1947]. A log-modulus plot is a plot of  $\log |G(j\omega)H(j\omega)|$  versus  $\angle G(j\omega)H(j\omega)$ . Lines of constant  $M$  and constant  $\alpha$ , where

$$M = |C(j\omega)/R(j\omega)| \quad \text{and} \quad \alpha = \angle C(j\omega)/R(j\omega) \quad (155.11)$$

are circles on the polar plot, become contours when drawn on the log-modulus plot. These  $M$  and  $\alpha$  contours are shown in Fig. 155.6.

**Figure 155.6** Log-modulus representation for lines of constant  $M$  and lines of constant  $\alpha$ .

Changing the gain  $K$  does not affect the phase angle, but merely moves the log-modulus plot  $G(j\omega)H(j\omega)/K$  for a system vertically up for  $K > 1$  and vertically down for  $K < 1$ . The  $M_p$  contour shown in Fig. 155.7 is the desired value of  $M_p$ . The solid curve is the log-modulus plot of  $G(j\omega)H(j\omega)/K$  for the system. The vertical distance that this curve must be raised such that it is tangent to the desired  $M_p$  contour is  $\log K$ . The dashed curve is the resultant frequency response  $G(j\omega)H(j\omega)$ . The frequency at the point of tangency is  $\omega_p$ .

**Figure 155.7** Determination of  $K$  for a desired  $M_p$ .

## 155.3 Gain Margin and Phase Margin

The  $-1$  point of the  $G(s)H(s)$  map has great significance with regard to the stability of a system. Figure 155.8 shows a typical  $G(j\omega)H(j\omega)$  plot in the vicinity of the  $-1$  point. If the gain were multiplied by an amount  $K_M$ , called the **gain margin**, the  $G(j\omega)H(j\omega)$  plot would go through the  $-1$  point. Thus, the gain margin is an indication of how much the gain can be increased before the  $G(j\omega)H(j\omega)$  plot goes through the critical point.

**Figure 155.8** Gain margin  $K_M$  and phase margin  $\gamma$  on the polar plot.

The angle  $\gamma$  in Fig. 155.8 is the angle measured from the negative real axis to the radial line through the point where the polar plot crosses the unit circle. If the angle  $\gamma$  were zero, the polar plot would go through the  $-1$  point. The angle  $\gamma$ , called the **phase margin**, is a measure of the closeness of the polar plot to the critical point. A positive phase margin indicates a stable system, as does a gain margin greater than one.

For the system shown in Fig. 155.1, the relationship between the damping ratio  $\zeta$  and the phase margin  $\gamma$  is

$$\zeta = \frac{\tan \gamma \sqrt{\cos \gamma}}{2} \quad (155.12)$$

A plot of this relationship is shown in Fig. 155.9(a). The frequency  $\omega_c$  at which the open-loop frequency response crosses the unit circle is

$$\omega_c/\omega_n = [\sqrt{4\zeta^4 + 1} - 2\zeta^2]^{1/2} \quad (155.13)$$

This relationship is shown in Fig. 155.9(b). By knowing the phase margin  $\gamma$ , the damping ratio  $\zeta$  may be determined from Fig. 155.9(a). From Fig. 155.9(b), the ratio  $\omega_c/\omega_n$  can be found. Thus, by knowing  $\omega_c$ , the natural frequency  $\omega_n$  can now be calculated. This method for ascertaining the damping ratio  $\zeta$  and natural frequency from the phase margin  $\gamma$  and the frequency  $\omega_c$  at which the open-loop frequency response crosses the unit circle yields good approximations for systems other than that shown in Fig. 155.1.

**Figure 155.9** Correlation between  $\zeta$ ,  $\omega_n$ , and phase margin  $\gamma$ : (a) plot of  $\gamma$  versus  $\zeta$ , and (b) plot of  $(\omega_c/\omega_n)$  versus  $\zeta$ .

## 155.4 Series Compensation

A change in the gain  $K$  changes the scale factor of the polar plot, but does not affect the basic shape of the plot. In the design of control systems, it is often necessary to change the shape of the polar plot in order to achieve the desired dynamic performance. A common way of doing this is to insert elements in series with the feedforward portion of the control, as is illustrated by the elements  $G_c(j\omega)$  shown in Fig. 155.10. This method of compensating the performance of a control system is called **cascade** or **series compensation**.

**Figure 155.10** Series compensator  $G_c(j\omega)$ .

## Lead Compensation

The frequency response of a phase lead compensator is

$$\frac{1 + j\tau_1\omega}{1 + j\tau_2\omega} \quad \tau_1 > \tau_2 \quad (155.14)$$

The asymptotic approximation to the Bode diagram [Bode, 1945] for  $(1 + j\tau_1\omega)/(1 + j\tau_2\omega)$  is shown in Fig. 155.11. The frequency at which the maximum phase lead occurs is at

$$\omega_m = 1/\sqrt{\tau_1\tau_2} \quad (155.15)$$

The value of the maximum phase lead is

$$\phi_m = \tan^{-1} \frac{(\tau_1/\tau_2) - 1}{2\sqrt{\tau_1/\tau_2}} \quad (155.16)$$

Figure 155.12 shows a plot of  $\phi_m$  versus both  $\log \tau_1/\tau_2$  and  $\tau_1/\tau_2$ .

**Figure 155.11** Bode diagram for a phase lead compensator.

**Figure 155.12** Lead compensator characteristics: maximum phase shift  $\phi_m$  versus  $\log \tau_1/\tau_2$ .

The effect of using a phase lead compensator in series with the feedforward portion of a control system is illustrated in Fig. 155.13. The dashed curve is the frequency response  $G(j\omega)H(j\omega)$  for the uncompensated control system. This system is unstable. The addition of the lead compensation  $G_c(j\omega)$  to reshape the high frequency portion of the polar plot is shown by the solid line curve. Note that lead compensation rotates a typical vector such as that for  $\omega = 2$  in a counterclockwise direction away from the  $-1$  point. Because of the counterclockwise rotation, lead compensation has the very desirable effect of increasing the natural frequency, which increases the speed of response of the system.

**Figure 155.13** Use of phase lead to reshape a polar plot.

To select a lead compensator, it is necessary to specify the values of both  $\tau_1$  and  $\tau_2$ . Because of the two unknowns  $\tau_1$  and  $\tau_2$ , the selection of a lead compensator to achieve desired design specifications is basically a trial-and-error process. However, a systematic procedure which rapidly converges is described in the following steps.

1. Determine the phase margin for the uncompensated system.
2. Select a value for  $\phi_m$  which is the difference between the desired phase margin and the value obtained in step 1, plus a small additional amount, such as  $5^\circ$ .
3. Determine the ratio  $\tau_1/\tau_2$  from Fig. 155.12.
4. Determine the frequency where the log magnitude for the uncompensated system is  $-0.5 \log(\tau_1/\tau_2)$ . Use this frequency for  $\omega_m$ .
5. Because the phase lead compensator provides a gain of  $0.5 \log(\tau_1/\tau_2)$  at  $\omega_m = 1/\sqrt{\tau_1\tau_2}$ , this will be the frequency where the compensated system crosses the unit circle. Determine the resulting phase margin for the compensated system.

If the phase margin is too small, increase the value  $\tau_1/\tau_2$  and, if it is too large, decrease the ratio  $\tau_1/\tau_2$  and then repeat the steps.

## Lag Compensation

The frequency response for a phase lag compensator is

$$\frac{1 + j\tau_2\omega}{1 + j\tau_1\omega} \quad \tau_1 > \tau_2 \quad (155.17)$$

The Bode diagram for  $(1 + j\tau_2\omega)/(1 + j\tau_1\omega)$  is shown in Fig. 155.14. Note that when  $\omega = 10/\tau_2$ , the negative phase shift  $\phi_c$  is very small. The negative phase shift associated with lag compensation is usually undesirable. The effectiveness of lag compensation is attributed to the attenuation ( $-\log \tau_1/\tau_2$ ) that occurs at high frequencies.

**Figure 155.14** Bode diagram for a lag compensator.

The effect of using a phase lag compensator in series with the feedforward portion of a control system is illustrated in Fig. 155.15. The dashed curve is the frequency response of the uncompensated system. Note that the effect of lag compensation is to shorten a typical vector, such as that for  $\omega = 0.5$ , and to rotate it slightly in a counterclockwise direction. A procedure for determining the lag compensator for obtaining a desired dynamic performance is described in the following steps.

1. Add  $5^\circ$  to the desired phase margin and then subtract  $180^\circ$  from this result.
2. For the uncompensated system, determine the value of the  $\log |G(j\omega)H(j\omega)|$  at the angle determined in step 1.
3. Set this value of  $\log |G(j\omega)H(j\omega)|$  equal to  $\log \tau_1/\tau_2$ . When the lag compensator is added to the uncompensated system, this will be the point where the resultant system crosses the unit circle (i.e.,  $\log |G(j\omega)H(j\omega)| - \log \tau_1/\tau_2 = 0$ ). This will be the  $10/\tau_2$  frequency.

**Figure 155.15** Use of phase lag to reshape a polar plot.

## Lag-lead Compensation

A lag-lead compensator is a series combination of a lag and a lead network. The general transfer function for **lag-lead compensation** is

$$\frac{1 + jc\tau_2\omega}{1 + jc\tau_1\omega} \frac{1 + j\tau_1\omega}{1 + j\tau_2\omega} \quad \tau_1 > \tau_2 \quad (155.18)$$

Rather than using a lag and a lead compensator in series, it is possible to use a single compensator. The Bode diagram for a typical lag-lead compensator is shown in [Fig. 155.16 \[Palm, 1986\]](#).

Because  $c\tau_1 > c\tau_2 > \tau_1 > \tau_2$ , the lag compensation takes place before and at lower frequency than the lead compensation. A factor of five provides a reasonable separation between the lag and lead compensations:

$$\frac{1}{\tau_1} = 5 \frac{1}{c\tau_2}$$

or

$$c = 5 \frac{\tau_1}{\tau_2} \quad (155.19)$$

The maximum phase shift  $\phi_m$  occurs at  $\omega = 1/\sqrt{\tau_1 \tau_2}$ , and the corresponding gain is  $-0.5 \log \tau_1/\tau_2$ . This is the same as for a lead compensator, except that the sign of the gain  $0.5 \log \tau_1/\tau_2$  is negative. This feature makes the lag-lead compensator considerably more effective than the lead compensator only.

**Figure 155.16** Bode diagram for a lag-lead compensator.

## 155.5 Internal Feedback

Another method commonly used to alter frequency response characteristics is that of providing a separate **internal feedback** path about certain components [D'Souza, 1988]. A plot of the function  $G^{-1}(j\omega) = 1/G(j\omega)$  is called an inverse polar plot. Figure 155.17 shows a typical inverse polar plot for the function  $G^{-1}(j\omega)$ . At any frequency  $\omega$ , the vector from the origin to a point on the plot defines the vector  $G^{-1}(j\omega)$  for that frequency. The length of the vector is  $|G^{-1}(j\omega)| = 1/|G(j\omega)|$ , and the angle is

$$\angle G^{-1}(j\omega) = \angle \frac{1}{G(j\omega)} = -\angle G(j\omega) \quad (155.20)$$

**Figure 155.17** Typical inverse polar plot  $G^{-1}(j\omega)$ .

On the inverse plane, lines of constant  $M$  are circles of radius  $1/M$ . The center of these concentric  $M$  circles is at the point  $x = -1$  and  $y = 0$  (e.g., the  $-1$  point). A plot of the  $M$  circles on the inverse plane is shown in Fig. 155.18. Because the reciprocal of  $-1$  is still  $-1$ , this point has the same significance for an inverse polar plot as for a direct polar plot. The lines of constant  $\alpha = \angle[C(j\omega)/R(j\omega)] = -\angle[R(j\omega)/C(j\omega)]$  are radial straight lines (rays) which pass through the  $-1$  point.

**Figure 155.18**  $M$  circles and  $\alpha$  rays on the inverse plane.

As is illustrated in Fig. 155.19, the angle  $\psi$  of a radial line drawn from the origin and tangent to any  $M$  circle is

$$\sin \psi = 1/M \quad (155.21)$$

The general procedure for determining the required gain  $K$  to yield a desired  $M_p$  is as follows.

1. Plot the inverse function  $KG^{-1}(j\omega)H^{-1}(j\omega)$  .
2. Construct the tangent line at the angle  $\psi = \sin^{-1}(1/M_p)$  .
3. Construct the circle which is tangent to both the  $KG^{-1}(j\omega)H^{-1}(j\omega)$  plot and the tangent line.
4. The center of the circle is at the point  $-A$  . The desired gain is  $K = A$  .

When the function  $G^{-1}(j\omega)H^{-1}(j\omega)$  is plotted rather than  $KG^{-1}(j\omega)H^{-1}(j\omega)$  , then  $A$  is equal to the factor  $K_c$  by which the gain should be changed to yield the desired  $M_p$  .

**Figure 155.19** Tangent line to an  $M$  circle.

The major advantage of using the inverse plane is realized for systems with internal feedback. For the system of Fig. 155.20,

$$G^{-1}(j\omega) = \frac{1 + G_1(j\omega)H_1(j\omega)}{G_1(j\omega)} = G_1^{-1}(j\omega) + H_1(j\omega) \quad (155.22)$$

As is illustrated in Fig. 155.21, the vectors  $G_1^{-1}(j\omega)$  and  $H_1(j\omega)$  may be added as vector quantities to yield  $G^{-1}(j\omega)$  . For a given  $G_1^{-1}(j\omega)$  plot,  $H_1(j\omega)$  may be determined to move any given point to a desired location, such as a point of tangency with an  $M_p$  circle, or to yield a desired phase margin.

**Figure 155.20** Internal feedback  $H_1(s)$  placed about  $G_1(s)$ .

**Figure 155.21** Vector addition of  $G_1^{-1}(j\omega)$  and  $H_1(j\omega)$  to yield  $G^{-1}(j\omega)$ .

If  $H_1(s) = \alpha$  a constant, then the  $G^{-1}(j\omega)$  plot is shifted to the right by the distance  $\alpha$ . If  $H_1(s) = \beta s$ , then  $H_1(j\omega) = j\beta\omega$ , and the  $G^{-1}(j\omega)$  plot is shifted upwards vertically in proportion to the frequency  $\omega$ . If  $H(s) = \alpha + \beta s$ , then the  $G^{-1}(j\omega)$  plot is shifted both to the right and upwards vertically.

## 155.6 Compensation on the $S$ Plane

The transfer function for a phase lead compensator may be written in the form

$$\frac{1 + \tau_1 s}{1 + \tau_2 s} = \frac{s + 1/\tau_1}{s + 1/\tau_2} = \frac{s - z}{s - p} \quad \tau_1 > \tau_2 \quad (155.23)$$

where  $z = -1/\tau_1$  is a zero, and  $p = -1/\tau_2$  is a pole. The root locus plot for the system whose characteristic equation is  $s(s - r_1)(s - r_2) + K = 0$  is shown in Fig. 155.22(a). Assume that the root locus plot goes through the root location for the dominant roots (point  $a \pm jb$ ) shown in Fig. 155.22(b). The zero is drawn directly under the point  $a + jb$ . Application of the angle condition gives

$$\phi_1 + \phi_2 + \phi_3 + \phi_p - 90^\circ = 180^\circ$$

Hence,

$$\phi_p = 270^\circ - (\phi_1 + \phi_2 + \phi_3)$$

The angle  $\phi_p$  determines the location of the pole. Similarly, phase lag and lag-lead compensators [Dorf, 1989] may be designed on the  $s$  plane.

**Figure 155.22** (a) Root locus plot for  $s(s - r_1)(s - r_2) + K = 0$ , and (b) addition of phase lead compensation.

## HAROLD HAZEN AND THE THEORY OF SERVOMECHANISMS

Before the 1930s, feedback controls mostly concerned regulators and governors—devices to keep motion steady and stable. That changed in 1934, when Harold Hazen published "Theory of Servo Mechanisms" in the *Journal of the Franklin Institute*. This paper provided a consistent taxonomy of feedback devices (relay, pulsed, and continuous) and laid out a "transient analysis" approach for designing servos with specified response. It also noted that the theory of servomechanisms can be applied to the speed control of steam turbines and water wheels, the stabilization of ships by gyroscopes, the operation of gyrocompass repeaters, the automatic stabilization and guiding of aircraft, and "in fact the automatic recording or control of almost any measurable or measurable and controllable physical quantity." Hazen shifted the emphasis of control engineering from static to dynamic behavior, from regulation to control, and from diverse approaches in different applications to a single approach based on a unified view of dynamic systems.

## Defining Terms

**Cascade compensation:** The insertion of elements in series with the feedforward portion of a control system in order to obtain the desired performance.

**Compensation:** The method of improving the performance of a control system by inserting an additional component within the structure of the system.

**Damping ratio:** A dimensionless number which is a measure of the amount of damping in a system.

**Gain margin:** If the gain of a system were changed by this factor, called the gain margin, the  $G(j\omega)H(j\omega)$  plot would go through the -1 point.

**Internal feedback:** The method of system compensation in which an internal feedback path is provided about certain components.

**Lag compensation:** A component that provides significant attenuation over the frequency range of interest.

**Lag-lead compensation:** A component that provides both significant positive phase angle and attenuation over the frequency range of interest.

**Lead compensation:** A component that provides significant positive phase angle over the frequency range of interest.

**Natural frequency:** The frequency at which a system would oscillate if there was no damping.

**Phase margin:** The angle measured from the negative real axis to the radial line where the polar plot crosses the unit circle.

**Series compensation:** The insertion of elements in series with the feedforward portion of a control system in order to obtain the desired performance.

### 156.1 Control Performance and Design Decisions

Single-Variable Control • Multiple Variables with One Dependent Controlled Variable • Multiple Input-Output Control

**Thomas E. Marlin**

*McMaster University*

Process control addresses the application of automatic control theory to the process industries. These industries typically involve the continuous processing of fluids and slurries in chemical reactors, physical separation units, combustion processes, and heat exchangers in industries such as chemicals, petroleum, pulp and paper, food, steel, and electrical power generation. These industries share some general characteristics that influence the control application. First, the process design and operating conditions impose fundamental limits on the best possible control performance, so that the engineer should strive to design processes and select variables that are inherently easiest to control. Second, the control structure—that is, the measured and manipulated variables—must be selected from the large number of candidates. Third, the control algorithms must be matched to the control structure selected. Fourth, the processes tend to be highly nonlinear and difficult to model accurately using first principles because of the complex physiochemical systems; these complex and time-varying dynamics require all control designs and applications to explicitly consider robustness to ensure stability and performance over the expected range of conditions.

### 156.1 Control Performance and Design Decisions

---

Generally, the goal of process control is to reduce the variability of key process variables by adjusting selected manipulated variables, thereby moving variability to less important areas of the process. In evaluating control performance, many factors are relevant, as shown in [Fig. 156.1](#). First, the controlled variable should have a small deviation from its set point (or reference value); this can be measured by the integral of the error squared,  $\int (SP - CV)^2 dt$ , for short data sets and by the variance of the error for long data sets. In addition, the behavior of the manipulated variable is crucial, as large variance of this variable could lead to propagation of disturbances or to damage of process equipment. Most importantly, the stability and performance should remain acceptable for expected changes in the process dynamics; these changes are due to unavoidable errors in empirical identification and to changes in operating conditions such as production rate. Thus, the application of process control must satisfy a complex, multiobjective performance measure.

**Figure 156.1** Example control loop dynamic response.

Process control design requires many decisions to meet the demands of the process industries; these typically are (1) selecting sensors that reflect process performance, (2) selecting final elements with good dynamic responses and sufficient range, (3) ensuring that the feedback process

dynamics are favorable to good control performance, (4) selecting a structure for linking controlled and manipulated variables, and (5) selecting algorithms and tuning parameters to give robust performance. These decisions will be reviewed for single-variable and multivariable control.

## Single-Variable Control

Many complex control systems involve multiple, single-loop controllers; thus, the principles of single-loop control must be mastered as a basis for realistic, multivariable control systems. In these systems one measured variable is regulated by adjusting one manipulated variable. In most cases the algorithm used is the proportional-integral-derivative (PID) controller, which is given for a continuous system:

$$MV = K_c \left( E + \frac{1}{T_I} \int_0^t E \, dt' + T_D \frac{dE}{dt} \right) \quad (156.1)$$

with the error,  $E = SP - CV$ . Both the process and the controller appear in the closed-loop system and influence the control performance. To consider the behavior of the system, see the simple block diagram in [Fig. 156.2](#). In this example the dynamics between the manipulated variable and the outlet controlled variable have been approximated by a first order with dead time linear model, as can many overdamped systems of higher order. The transfer functions for the process (including sensor and final element dynamics) and the controller are given as follows:

$$\begin{aligned} \text{Feedback process:} \quad \frac{CV(s)}{MV(s)} &= \frac{K_p e^{-\theta s}}{\tau s + 1}; \\ \text{Disturbance:} \quad \frac{CV(s)}{D(s)} &= \frac{K_D e^{-\theta_D s}}{\tau_D s + 1} \end{aligned} \quad (156.2)$$

$$\text{Controller:} \quad \frac{MV(s)}{E(s)} = K_c \left( 1 + \frac{1}{T_I s} + T_D s \right) \quad (156.3)$$

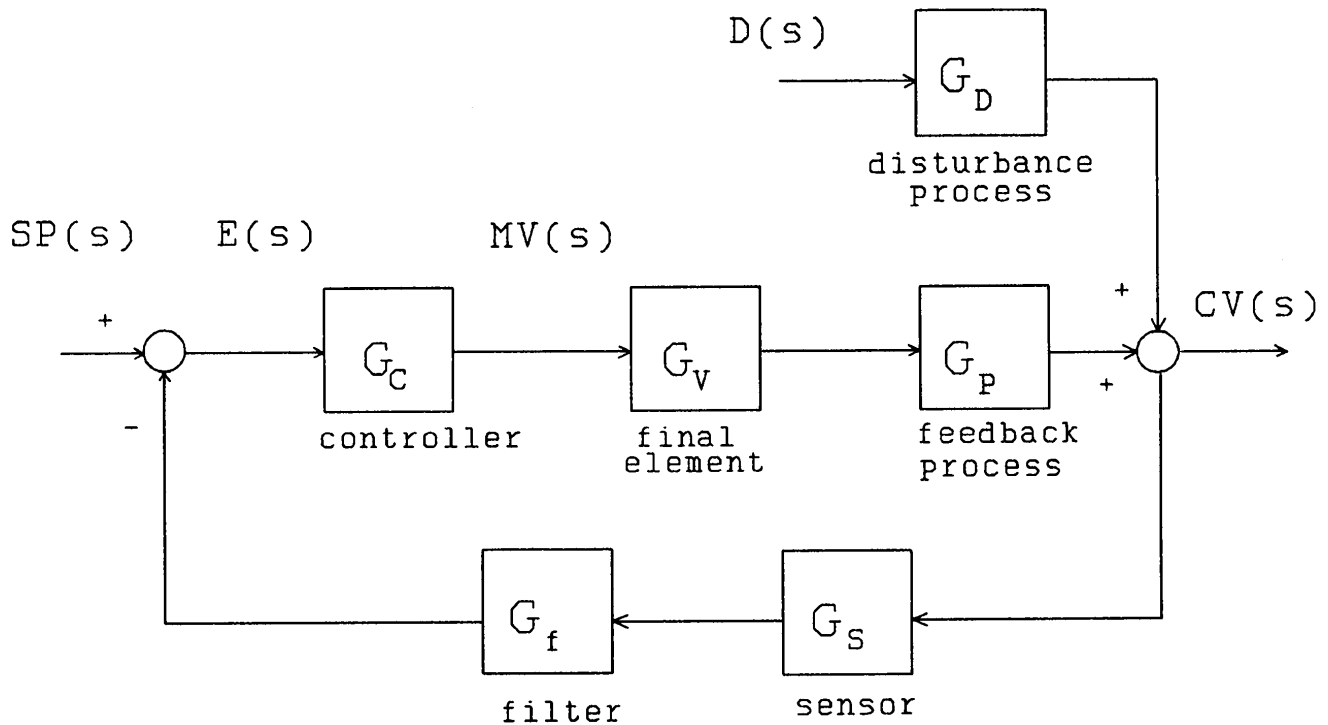

The transfer function describing the relationship between the disturbance and the controlled variable is

$$\frac{CV(s)}{D(s)} = \frac{G_D(s)}{1 + G_p(s)G_v(s)G_c(s)G_f(s)G_s(s)} \quad (156.4)$$

The stability of the closed-loop system depends on the terms in the characteristic equation, the denominator of the closed-loop transfer function; generally, the slower the dynamics of the elements in the feedback process, the less aggressive the feedback controller for stable behavior. Many methods for tuning the PID controller have been proposed—for example, the

Ziegler-Nichols method [1942]—although many suffer from poor robustness. Methods described in Fertik [1975] and Marlin [1994] provide better robustness.

**Figure 156.2** Single-loop block diagram.

The performance of the system depends on all terms in Eq. (156.4), and important insights can be obtained by considering the frequency response of  $|CV(j\omega)|/|D(j\omega)|$  from Eq. (156.4), shown in Fig. 156.3. For disturbances with very low frequencies, feedback control is much faster than the disturbance, and feedback is thus quite effective. For very high frequencies the disturbance time constant attenuates the effect of the disturbance on the controlled variable, and the performance is quite good, although not due to feedback compensation. In some intermediate range of frequencies, resonance occurs and feedback control performance is not generally very good. The location of the resonance peak depends on the feedback dynamics and the feedback controller.

**Figure 156.3** Closed-loop frequency response.

A summary of the effects of various elements in the feedback loop on the performance of single-loop control is given in [Table 156.1](#). This table provides the basis for design decisions to improve control. The process provides the most important limits to feedback control performance. It is important to note that large dead times and time constants in the feedback loop are always detrimental, whereas large time constants in the disturbance path can improve control performance.

## Multiple Variables with One Dependent Controlled Variable

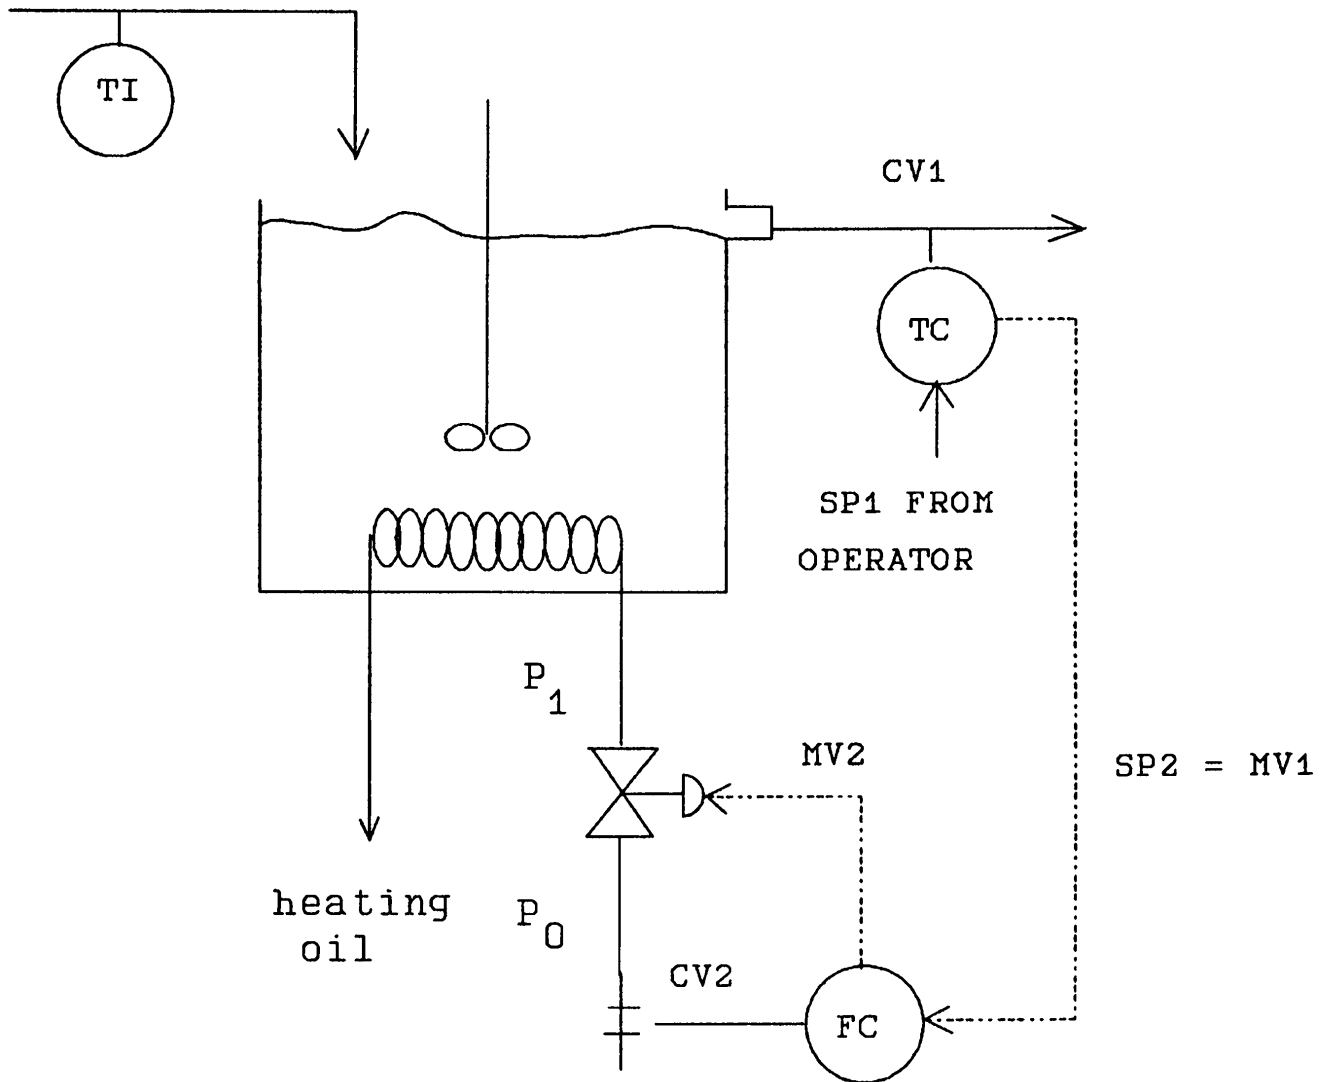

The control performance of a single variable can be improved by applying the results in [Table 156.1](#), without changing the process, by modifying the control structure. Since the feedback process dynamics impose the greatest limit on good performance, the two modified structures described here reduce the feedback dynamics between the manipulated and the controlled variables. The first new structure is **cascade** control, which uses a secondary measured variable to provide an early indication of selected disturbances. As shown in [Fig. 156.4](#), the secondary variable, the measured heating medium flow rate, is controlled using feedback principles, and the set point of the flow controller is adjusted via feedback to achieve the desired outlet temperature. Each of the controllers can use the PID controller algorithm, and the inner or secondary controller must be tuned first. The cascade design provides good performance for only some disturbances; for example, the design in [Fig. 156.4](#) gives good performance for disturbances in the pressure of the heating medium source, but it does not improve performance for inlet temperature disturbances.

**Table 156.1** Summary of Factors Affecting Single-Loop PID Controller Performance

Key Factor	Typical Parameter	Effect on Control Performance
Feedback process gain	$K_p$	The key factor is the product of the process and controller gains. For example, a small process gain can be compensated by a large controller gain. Note that the manipulated variable must have sufficient range.
Feedback process "speed"	$\theta + \tau$	Control performance is always better when this term is small.
Feedback fraction process dead time	$\frac{\theta}{\theta + \tau}$	Control performance is always better when this term is small.
Inverse response	Numerator term in transfer function, $(\tau s + 1)$ with $\tau < 0$	Control performance degrades for large inverse response.
Magnitude of disturbance effect	$K_d  \Delta D $	Control performance is always better when this term is small.
Disturbance dynamics	$\tau_D$	Control performance is best when the disturbance is slow, that is, the time constant is large.
	$\omega_D$	Feedback control is effective for low frequency disturbances and is least effective at the resonant frequency.
	$\theta_D$	Disturbance dead time does not influence performance.
Sensor		Measurement should be accurate. Dynamics should be fast with little noise.
Filter, $1/(1+\tau_f s)$	$\tau_f / (\theta + \tau)$	Filters higher frequency components of measurement. Reduces the variability of the manipulated variable but degrades control as filter time constant is increased.
Final element		Dynamics should be fast without sticking or hysteresis.
		Range should be large enough for response to demands.
Controller execution period ( $\Delta t$ )	$\frac{\Delta t}{\theta + \tau}$	Control performance is best when this parameter is small. Continuous PID tuning correlations can be used by modifying the dead time, $\theta' = \theta + \Delta t/2$ .
Controller tuning	$K_c K_p$	Determined from tuning correlations based on control objectives.
	$\frac{T_I}{(\theta + \tau)}$ $\frac{T_D}{(\theta + \tau)}$	
Modeling errors		Errors in identifying the process model parameters leads to poorer control performance and, potentially, instability. Tuning should consider the estimate of model errors.
Limitations on manipulated variables	$\min < mv(t) < \max$	Limitations on manipulated variables reduce the operating window, that is, the range of achievable conditions. An active limit would cause steady state offset from the set point.

**Figure 156.4** Cascade control system. (Source: Marlin, T. 1994. *Process Control: Designing Processes and Control Systems for Dynamic Performance*. McGraw-Hill, New York. With permission.)

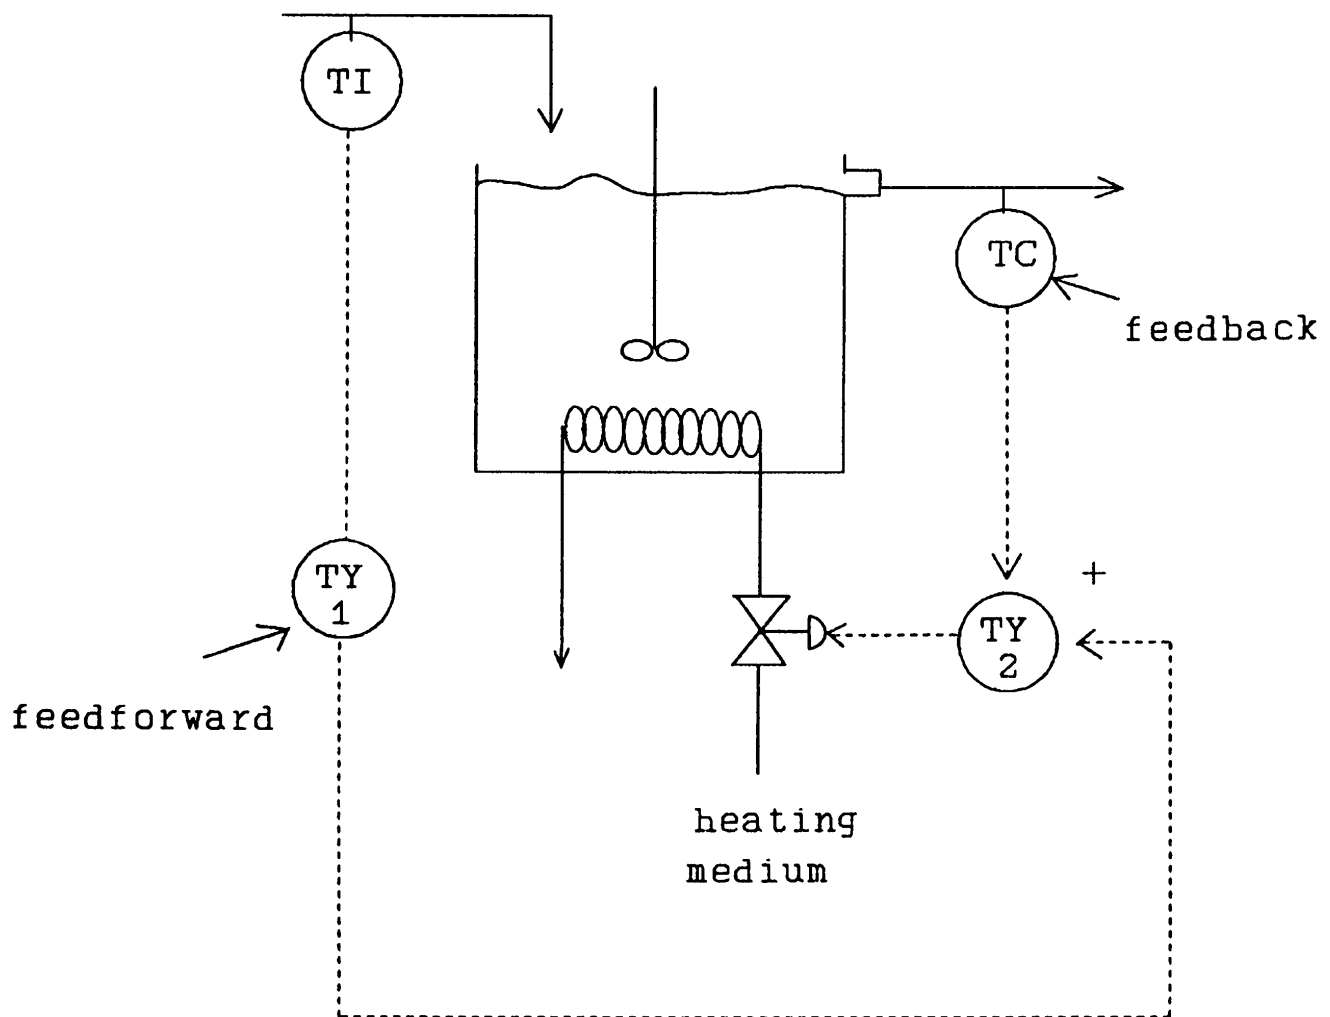

The second structural control modification provides an alternative to feedback by measuring the disturbance before it influences the process. This **feedforward** modification, shown in Fig. 156.5, eliminates the feedback dynamics from the control compensation for the measured disturbance and can theoretically provide excellent control. The feedforward control algorithm to give perfect feedforward compensation can be determined from block diagram algebra to be  $G_{ff}(s) = -G_D(s)/G_p(s)$ ; thus, the feedforward algorithm depends on the models of the process dynamics. When both the process and disturbance transfer functions can be well approximated by first order with dead time transfer functions, the feedforward controller is

$$G_{ff}(s) = \frac{MV(s)}{D(s)} = \frac{K_d}{K_p} \left( \frac{\tau s + 1}{\tau_D s + 1} \right) e^{-(\theta_D - \theta)s} \quad (156.5)$$

Equation (156.5) is often used for feedforward control and can be realized using standard gain, dead time, and lead/lag algorithms. Usually, feedback control is retained because feedforward

compensates for only the measured disturbance(s) and because the feedforward control is perfect only when the models are exact. The feedforward and feedback adjustments can be added, as in Fig. 156.5, using the property of linearity.

**Figure 156.5** Feedforward-feedback control system. (Source: Marlin, T. 1994. *Process Control: Designing Processes and Control Systems for Dynamic Performance*. McGraw-Hill, New York. With permission.)

## Multiple Input-Output Control

Most industrial processes involve many manipulated and controlled variables. Often, multiple single-loop controllers are used to automate the process; thus, the algorithms are identical to those introduced in the previous sections. However, the existence of **interactions** dramatically increases the difficulty of analysis and design. For the simple two input–two output system in Fig. 156.6, each input can influence all outputs [when  $G_{ij}(s) \neq 0$  for  $i \neq j$ ]. As a result the closed-loop

transfer function is

$$\frac{CV_1(s)}{SP_1(s)} = \frac{G_{c1}(s)G_{11}(s) + G_{c1}(s)G_{c2}[G_{11}(s)G_{22}(s) - G_{12}(s)G_{21}(s)]}{CE(s)} \quad (156.6)$$

with

$$CE(s) = 1 + G_{c1}(s)G_{11}(s) + G_{c2}(s)G_{22}(s) + G_{c1}(s)G_{c2}(s)[G_{11}(s)G_{22}(s) - G_{12}(s)G_{21}(s)]$$

Thus, interaction affects the stability of the closed-loop system, requiring modifications to the controller tuning, usually requiring the feedback action to be less aggressive. In addition, interaction can significantly modify the range of achievable steady state operating conditions, termed the *operating window*, and it can even affect whether a set of dependent variables can be controlled by adjusting a set of manipulated variables. Finally, interaction can significantly affect the dynamic control performance.

**Figure 156.6** Multiloop ( $2 \times 2$ ) block diagram.

The first, and often the most important, control design decision is the manner in which the controllers link the controlled and manipulated variables, termed *loop pairing*. The proper loop pairing should yield a control system that can achieve the desired operating window, control all variables independently, provide stable control with the same controller gain signs as for each single-loop system, provide stable performance when some loops are not in operation, and provide good performance for the most likely disturbances. The ability of the system to control the desired output variables depends on the process model given as follows:

$$\begin{bmatrix} CV_1(s) \\ CV_2(s) \end{bmatrix} = \begin{bmatrix} G_{11}(s) & G_{12}(s) \\ G_{21}(s) & G_{22}(s) \end{bmatrix} \begin{bmatrix} MV_1(s) \\ MV_2(s) \end{bmatrix} + \begin{bmatrix} G_{d1}(s) \\ G_{d2}(s) \end{bmatrix} D(s) \quad (156.7)$$

The controlled variables can be maintained exactly at their desired values if the feedback process can be inverted [Rosenbrock, 1974]. That is,

$$\det \begin{bmatrix} G_{11}(j\omega) & G_{12}(j\omega) \\ G_{21}(j\omega) & G_{22}(j\omega) \end{bmatrix} \neq 0 \quad (156.8)$$

Usually, the inverse cannot be taken because of the process dynamics (e.g., dead times), so *perfect* control is not possible. If the requirement is only that the controlled variables can be maintained at their desired values in the *steady state*, the requirement for controllability is

$$\det \begin{bmatrix} G_{11}(0) & G_{12}(0) \\ G_{21}(0) & G_{22}(0) \end{bmatrix} = \begin{bmatrix} K_{11} & K_{12} \\ K_{21} & K_{22} \end{bmatrix} \neq 0 \quad (156.9)$$

The criterion in Eq. (156.9) must be satisfied for a process control system to return the controlled variables to their set points.

Before discussing further requirements, a quantitative measure of interaction, the relative gain array, is introduced [McAvoy, 1983]. The relative gain is defined as

$$\lambda_{ij} = \frac{\left\{ \frac{\partial CV_i}{\partial MV_j} \right\}_{MV_k = \text{const}, k \neq j}}{\left\{ \frac{\partial CV_i}{\partial MV_j} \right\}_{CV_k = \text{const}, k \neq i}} = \frac{\left\{ \frac{\partial CV_i}{\partial MV_j} \right\}_{\text{other loops open}}}{\left\{ \frac{\partial CV_i}{\partial MV_j} \right\}_{\text{other loops closed}}} \quad (156.10)$$

The relative gain indicates how interaction influences the steady state behavior of the process, with a value of 1.0 indicating no influence and large deviations from 1.0 indicating strong influence. The array is formed as a matrix of elements,  $\lambda_{ij}$ . The relative gain provides valuable information on the selection of the proper loop pairings; only those loop pairings with relative gains that are positive are usually considered appropriate designs. Systems with negative relative gains are disqualified since the stable multiloop system will be unstable if one or more controllers become inactive [McAvoy, 1983; Morari and Zafiriou, 1989]; this situation is termed *poor integrity*.

Other considerations for multiloop design involve control performance. First, the most important variables should be paired with manipulated variables that have sufficient range—that is, that can be adjusted to compensate for all expected disturbances. Second, all important variables should be paired with manipulated variables that provide fast feedback compensation. Third, the process equipment and operating conditions and the control structures should be selected to attenuate disturbances; this could include tankage before sensitive units and enhancements such as cascade control. Also, inventories (liquid levels and solid inventory) should be controlled in a manner that attenuates flow variation to downstream units. Fourth, inferential measurements should be used to provide real-time control where online sensors of the true controlled variable are not available.

Fifth, the loop pairings should provide the best control performance for the multiloop system; the proper pairing provides not only fast responses for each loop, but also interactions between the loops that improve the performance of the interacting loops. Favorable interaction can occur where one loop, while controlling a variable, introduces adjustments that also tend to reduce the variability of other interacting controlled variables. Both favorable and unfavorable interactions are possible; thus, the proper pairing selection is crucial. Methods are available for analyzing the likely effects of interaction [Skogestad and Morari, 1987; Marlin, 1994].

This brief summary provides some guidance on key aspects of applying automatic control in the process industries. The citations in "References" and "Further Information" provide details essential for successful process control design and application.

## Defining Terms

**Cascade:** A control structure in which one (primary) feedback controller sends its output to the set point of another (secondary) feedback controller.

**CV, MV, SP:** Symbols used for the controlled variable, manipulated variable, and the set point (reference value), respectively.

**Feedforward:** A control approach in which the adjustments to the manipulated variable are based on a measured input to maintain a system output unchanged.

**Interaction:** The situation in a multi-input, multioutput system where the inputs affect more than one output variable.

## Further Information

Many useful standards for industrial practice in process control are documented in *Standards and Practices for Instrumentation and Control*; 11th edition, 1992, published by the Instrument Society of America.

A crucial contribution of process control is improved plant safety. An introduction to approaches for designing safe process control is presented in *Guidelines for the Safe Automation of Chemical*

*Processes*, 1993, published by the American Institute of Chemical Engineers.

An introduction to advanced methods for empirical model identification is given in Cryor, 1986, *Times Series Analysis*, Duxbury Press.

Examples of the industrial practice of advanced process control are published in meetings organized by the International Federation of Automatic Control (IFAC), Symposia on ADCHEM, DYCORD, and Workshops on the Interaction Between Process Design and Control.

A topic of growing interest in process automation is statistical process control; a good introduction to issues and methods is given in Box and Kramer, 1992, Statistical process monitoring and feedback adjustment—A discussion, *Technometrics*, 34: 251–267, with further discussions on pages 268–285.

An alternative approach for multivariable control involves a centralized control algorithm, which is introduced in Garcia and Morshedi, 1986, Quadratic programming solution of dynamic matrix control (QDMC), *Chem. Eng. Commun.* 46:73–87.

With the decreasing cost of microcomputer systems caused by the development of very large scale integration (VLSI) technology, small, low-cost **digital computer** systems are being incorporated into low-cost automotive and home appliance systems. In the past these systems were routinely incorporated into aerospace, military, and industrial applications where their relative high cost could be tolerated. The growth of the field of digital control systems is best illustrated by the fact that two decades ago there were no computers in automobiles and now automobiles have more than two computers controlling, among other things, fuel injection, antilock brakes, active suspension, and interior climate.

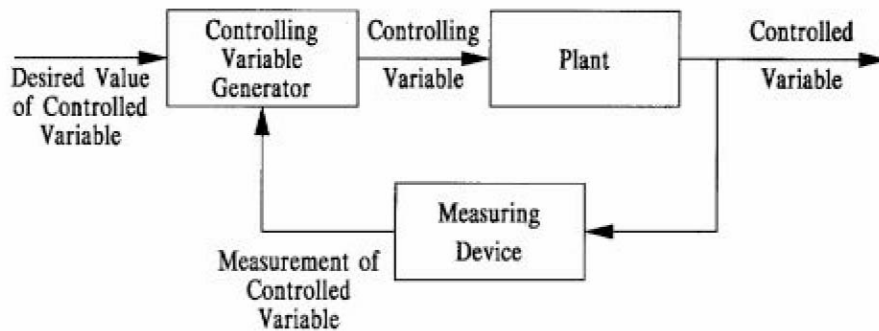

### 157.1 Feedback Control

---

In this section we shall be concerned with the idea of forcing the output of a dynamic system, called the *plant*, to take on a sequence of predetermined values in time. If a complete model of the system to be controlled is known and there are no unknown disturbances, then the input controlling variable may be manipulated to cause the output to take on the correct sequence of values. On the other hand, if the model of the system to be controlled is known only approximately or if there are unknown disturbances acting on the system (which there always are), then the output will deviate significantly from the desired values.

A better way to control such a plant is to make measurements of the output variable that are to be compared to the desired output; then the controlling variable is to be adjusted in such a way as to drive the plant output toward the desired value. This control strategy is shown diagrammatically in [Fig. 157.1](#).

**Figure 157.1** Closed-loop control strategy.

Such a control system is exemplified by a typical home heating system. There may be two controlling variables such that one drives the output one direction, whereas the other drives it in the opposite direction. One must be sure to design the controlling variable generator so that the correct action takes place.

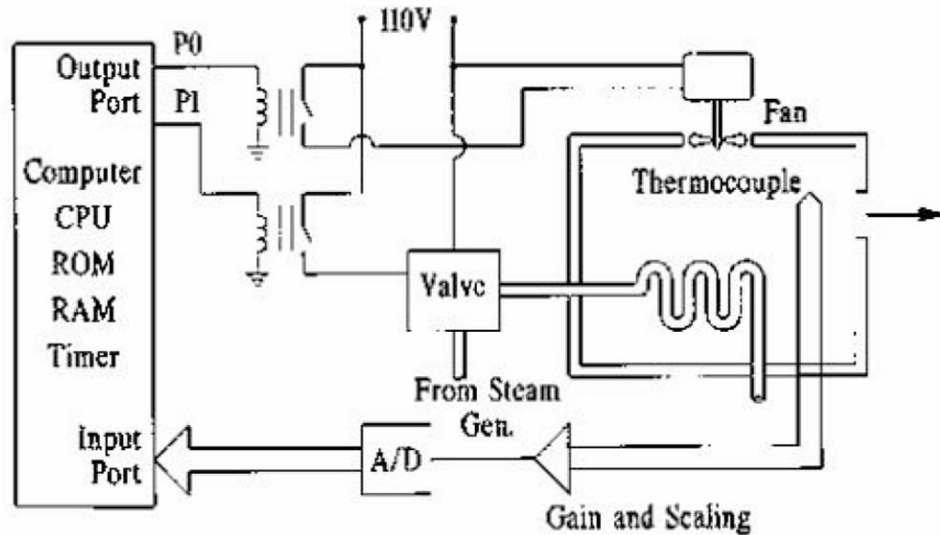

## 157.2 Digital Control

---

The previous closed-loop control scenario is entirely compatible with the incorporation of a digital processor into the control loop. The digital processor is particularly well suited to the task of control because it can process measurements in digital form to produce digital outputs that may be as simple as binary (on/off) signals. The measurement inputs can be in the form of either (1) analog-to-digital converter outputs (which are numerical samples of a signal), or (2) simply a binary signal that the controlled variable has exceeded some threshold value or that it has fallen below some other threshold value. This latter technique is particularly well suited to minimal hardware implementations because the processor can poll the bits of an input port for binary information about the controlled variable. Similarly, an output port can be employed to output simple on-off signals to control actuating elements such as valves, heaters, fan motors, and so on.

A typical application of the strategy just outlined is shown in [Fig. 157.2](#) for the control of the temperature of the interior of an environmental chamber. Disturbances to the system are changes in the exterior temperature from the normal expected temperature. The steam coils provide heat to raise the interior temperature, whereas the fan provides cool exterior air for decreasing the interior temperature.

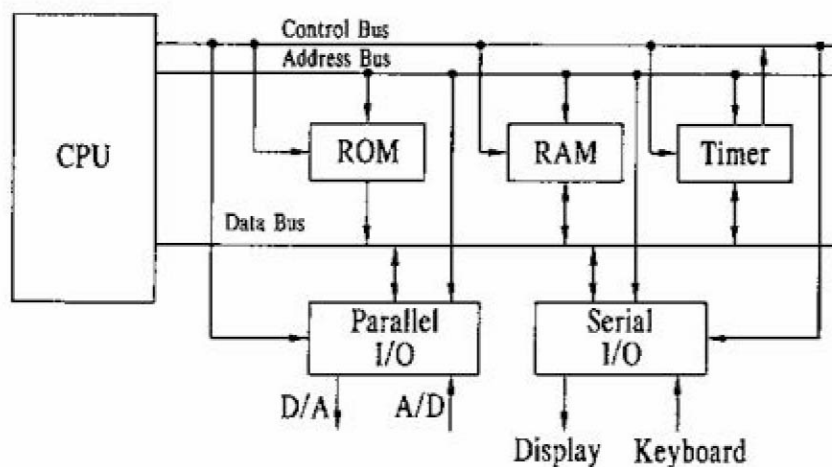

**Figure 157.2** Computer control of environmental chamber temperature.

### 157.3 Microcontroller Architecture

A microcomputer typical of those employed in control applications is illustrated in [Fig. 157.3](#). The computer consists of a central processing unit (CPU), random access memory (RAM), read-only memory (ROM), a timer, and serial and parallel I/O, all connected by three parallel buses that are functionally designated as the data bus, address bus, and control bus.

**Figure 157.3** Architecture of a typical digital control computer. (Source: Jacquot, R. G. 1995. *Modern Digital Control Systems*, 2nd ed. Marcel Dekker, New York. With permission.)

The major manufacturers of microprocessors—namely, Motorola and Intel—produce families of

microcontrollers that have many of the hardware components on board with the CPU, including both ROM and RAM, and in some instances there is also a multichannel analog-to-digital converter for acquisition of sensor data from the process or processes that are to be controlled. These microcontrollers have found wide acceptance in the automotive and appliance industries.

## 157.4 Linear Digital Control

---

Consider the case where the plant with continuous-time dynamics is driven by an output from a digital-to-analog converter (D/A) and the measurements of the plant variables are interfaced to the digital processor with an analog-to-digital converter (A/D). The case for a single controlling variable and a single controlled variable is illustrated in Fig. 157.4. In this case the A/D and D/A are operated synchronously and periodically. The A/D provides numerical values of periodic samples of the output variable  $y(t)$ . One such numerical value is commonly called  $y(kT)$ , where  $k$  denotes an integer such that  $t = kT$  and  $T$  is the sampling interval. The numbers output periodically to the D/A will be termed  $u(kT)$  and called the *control effort*. The error sequence is defined as

$$e(kT) = r(kT) - y(kT) \quad (157.1)$$

where  $r(kT)$  is the sequence of reference values that are the desired values of the output. The samples of the output  $y(kT)$  cannot perfectly track the  $r(kT)$  because of friction, inertia, or capacitance (thermal or fluid) in the plant. Present and past values of the error sequence and past values of the controlling sequence are combined to form the current value of the controlling variable. One way to combine these variables is to use a linear combination of the form

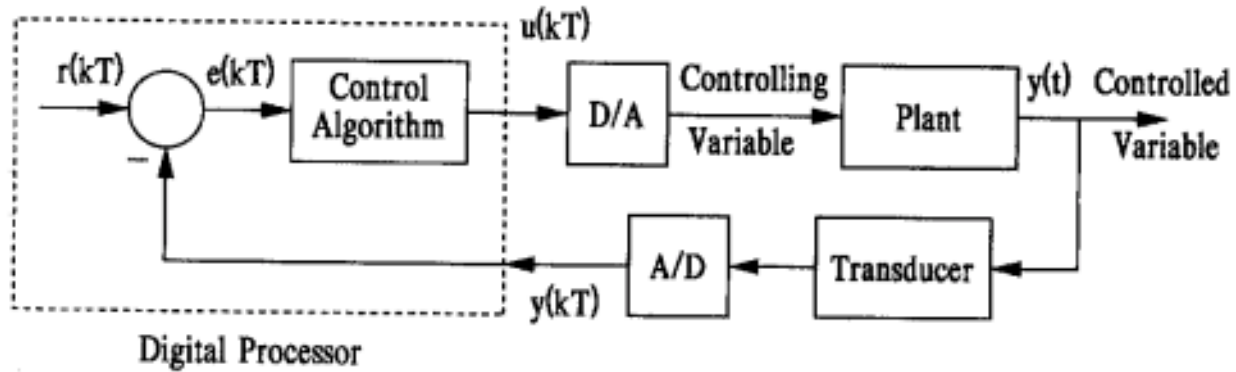

$$\begin{aligned} u(kT) = & b_n e(kT) + b_{n-1} e[(k-1)T] + \cdots + b_o e[(k-n)T] \\ & + a_{n-1} u[(k-1)T] + \cdots + a_o u[(k-n)T] \end{aligned} \quad (157.2)$$

The digital control design task is to determine the values of  $a_i$  and  $b_j$  to give the controlled system desirable performance. The simplest possible version of Eq. (157.2) is to use only the current error on the right side of the equation, which gives a control law:

$$u(kT) = b_n e(kT) \quad (157.3)$$

This control law is called the *proportional control strategy*, wherein the control action taken is proportional to the error—that is, the larger the error is, the larger the corrective action is. This is a sensible control strategy from the point of view that it always faces the plant in the direction to drive the error to zero. One problem with this strategy, however, is that if the constant  $b_n$  is too large the controller may tend to overcorrect and the result will be an unstable closed-loop system. There must therefore be some limitations on  $b_n$  for many systems to remain stable.

**Figure 157.4** Linear digital controller.

It is known in the study of analog control of systems that a controller that incorporates integral action can be very effective in the suppression of sustained errors; however, the integrator will also have a destabilizing effect on the closed-loop system. A compromise that will still control sustained errors and has more favorable stability properties is the proportional plus integral (PI) controller, which in continuous time has the form

$$u(t) = K_p e(t) + K_i \int_0^t e(\tau) d\tau \quad (157.4)$$

This control law can be approximated in the discrete-time domain by approximating the integral with trapezoidal numerical integration [Jacquot, 1995], resulting in the discrete-time control law of

$$u(kT) = u[(k-1)T] + b_1 e(kT) + b_0 e[(k-1)T] \quad (157.5)$$

where the order of the controller given by Eq. (157.2) has been selected as 1, and the coefficient  $a_0$  has been chosen as unity by virtue of the integral action. The values of  $b_1$  and  $b_0$  are the values to be selected in the course of the design process.

## 157.5 Digital Control Stability Analysis and Design

Thus far, stability and instability have only been discussed in passing; now we shall consider the analytical tools needed for design. The appropriate tool for discrete-time systems is the one-sided  $z$  transform. The  $z$  transform of a discrete-time sequence  $x(k)$  is defined by

$$X(z) = Z[x(k)] = \sum_{k=0}^{\infty} x(k)z^{-k} \quad (157.6)$$

There are many well-developed tables of  $z$  transforms; the reader is referred to one of the popular texts on the subject [Franklin *et al.*, 1990]. For linear plants with linear control laws such as those given by Eqs. (157.2), (157.3), and (157.5), the performance and stability analyses are best carried

out in the complex  $z$  plane.

If the plant is linear it can be characterized by a transfer function  $G(s)$ . If (1) the plant is driven by a digital-to-analog converter, (2) the output is sampled by an analog-to-digital converter, and (3) the two converters are operated synchronously by a common clock as illustrated in Fig. 157.5, then the plant and two converters comprise, from input to output, a discrete-time system with a transfer function [Jacquot, 1995]

$$G(z) = \left( \frac{z-1}{z} \right) ZL^{-1} \left[ \frac{G(s)}{s} \right] \quad (157.7)$$

where the  $ZL^{-1}$  operations reflect the  $z$  transform of the samples taken from the inverse transform of  $G(s)/s$ .

**Figure 157.5** Linear plant driven by a digital-to-analog converter with sampled output.

The linear feedback control law of Eq. (157.2) can be characterized as a  $z$ -domain transfer function  $D(z)$  of the form

$$D(z) = \frac{U(z)}{E(z)} = \frac{b_n z^n + \cdots + b_1 z + b_0}{z^n - a_{n-1} z^{n-1} - \cdots - a_1 z - a_0} \quad (157.8)$$

and the complete closed-loop system is shown in Fig. 157.6. The closed-loop characteristic equation can be shown to be

$$1 + G(z)D(z) = 0 \quad (157.9)$$

where  $G(z)$  and  $D(z)$  are the transfer functions defined, respectively, in Eqs. (157.7) and (157.8). The criterion for the stability of the closed-loop system is that the roots of Eq. (157.9) [those values of  $z$  that satisfy Eq. (157.9)] lie interior to the unit circle of the complex  $z$  plane.

**Figure 157.6** Complete closed-loop digital control system.

## ROV MEDEA/JASON

D. Mindell,

Massachusetts Institute of Technology

*Medea/Jason* is a remotely operated vehicle (ROV) system designed for scientific investigation of the deep ocean floor. It is a dual-vehicle system, with *Medea* serving as a wide area survey vehicle and *Jason* as a precision multisensory imaging and sampling platform. Both *Medea* and *Jason* are designed to operate to a maximum depth of 20000 feet (6000 meters), are transportable, and can be operated from a variety of vessels.

*Medea* is maneuvered primarily by movements of a ship utilizing dynamic positioning. *Jason* is designed for detailed survey and sampling tasks that require a high degree of maneuverability. It weighs about 2200 pounds (1000 kilograms) in air but is nearly neutrally buoyant at depth. The dynamics of *Jason* were designed to make it a very controllable platform. It is propelled by seven DC electric thrusters that provide about 300 newtons (70 pounds) in the vertical direction, 260 newtons (60 pounds) in the forward direction, and about 200 newtons (45 pounds) in the lateral direction. The vehicle has excellent passive stability in pitch and roll. (Courtesy of Woods Hole Oceanographic Institution.)

## 157.6 Computer-Aided Design

---

A convenient environment for the design of such systems is that of MATLAB™, in particular employing the Control System Toolbox. That environment is particularly useful for calculation of roots of characteristic polynomials resulting from Eq. (157.9) and the other associated frequency- and time-domain responses. The use of MATLAB has become the accepted computational environment for unified analysis, design and simulation, particularly, using the new graphical interface of SIMULINK. Another excellent simulation environment is that of VISSIM™, which is similar to SIMULINK in that it retains the analog computer device-oriented nature with which many engineers are familiar.

**Example.** Consider the control of the fluid level in the prismatic tank shown in Fig. 157.7. The flow rate  $Q$  into the tank will be controlled by a digital-to-analog converter and the fluid level  $h$  will be sampled periodically with period  $T$  with an analog-to-digital converter. The fluid will be considered to be incompressible, and the principle of conservation of volume yields

$$A \frac{dh}{dt} = -C(h)^{1/2} + Q(t) \quad (157.10)$$

where  $Q(t)$  is the incoming volumetric flow rate,  $A$  is the tank area, and  $h(t)$  is the instantaneous fluid level. Consider perturbations in the fluid level about some equilibrium height  $H$  with steady inlet flow of  $U$  and denote the perturbations in these two variables as  $y(t)$  and  $u(t)$ , respectively. The equation becomes

$$A \frac{dy}{dt} = -K(H + y)^{1/2} + U + u(t) \quad (157.11)$$

The nonlinear term on the right side may be approximated for ( $y \ll H$ ) by the first two terms of a binomial expansion. After dropping the equilibrium flow terms the resulting differential equation in the perturbation variables is

$$A \frac{dy}{dt} = -\frac{C}{2(H)^{1/2}} y + u(t) \quad (157.12)$$

This linear differential equation will have a corresponding transfer function

$$G(s) = \frac{Y(s)}{U(s)} = \frac{1/A}{s + (1/\tau)} \quad (157.13)$$

where  $\tau = 2(H)^{1/2} A/C$  is the system time constant. If the data converters are considered, then the discrete-time transfer function from flow-rate perturbation to sampled height perturbation is given by Eq. (157.7) to be

$$G(z) = \frac{\tau}{A} \left[ \frac{1 - e^{-T/\tau}}{z - e^{-T/\tau}} \right] \quad (157.14)$$

If a proportional controller with gain  $K$  is chosen, then  $D(z) = K(K > 0)$  and the closed-loop characteristic equation from Eq. (157.9) is

$$1 + \frac{K\tau}{A} \left[ \frac{1 - e^{-T/\tau}}{z - e^{-T/\tau}} \right] = 0 \quad (157.15)$$

The system will be stable so long as the root of Eq. (157.15) lies interior to the unit circle, and hence it is stable if

$$\frac{K\tau}{A} < \left[ \frac{1 + e^{-T/\tau}}{1 - e^{-T/\tau}} \right] \quad (157.16)$$

If the sampling period is chosen to be one fifth of the time constant ( $\tau/T = 5$ ) then the limiting value of  $K\tau/A$  is 10.03. If  $K\tau/A$  is chosen as 8 and the initial value of the perturbation height is  $y_o$ , then the response of the system is as shown in Fig. 157.8.

**Figure 157.7** Fluid tank for level control.

**Figure 157.8** Fluid height and input flow-rate perturbations for the fluid level control system.

## Defining Terms

**Digital computer:** A collection of digital devices including an arithmetic logic unit (ALU), read-only memory (ROM), random access memory (RAM), and control and interface hardware.

**Feedback control:** The regulation of a response variable of a system in a desired manner using measurements of that variable in the generation of the strategy of manipulation of the controlling variables.

The Robotics Industry Association defines a robot as a "reprogrammable multifunctional manipulator designed to move material, parts, tools, or specialized devices, through variable programmed motions for the the performance of a variety of tasks." A robotic manipulator generally consists of a serial chain of links connected via revolute or prismatic joints and actuated via gear trains or directly by electric motors or hydraulic or pneumatic drives. A robotic system will generally include position sensors (potentiometers, optical encoders, etc.) and may also include contact, tactile, force/torque, proximity, or vision sensors. The manipulator is typically fitted with an end effector, such as a gripper or hand, to enable it to accomplish the desired task. An example of an industrial robot is the PUMA 560 shown in [Fig. 158.1](#). The fundamental control problem in robotics is to determine the required actuator signals such that the desired motion is executed in accordance with specified performance criteria. If the robot is to perform a task while in contact with a surface, it is also necessary to control the contact force applied by the manipulator. Although the control problem is simply stated in the preceding, its solution may be quite complicated, since a robot's dynamics are described by a set of coupled nonlinear differential equations.

**Figure 158.1** PUMA 560 Robot. (*Source: Stäubli Unimation, Inc. 1985. PUMA Mark II Robot 500 Series Equipment Manual, pp. 1–3. Stäubli Unimation, Inc., Sewickly, PA. With permission.*)

**Figure 158.1**

The planning of the manipulator trajectory to achieve the desired motion is integrally linked to the control problem. The position of the robot can be described in joint space by the set of joint coordinates or in **Cartesian or task space** by the position and orientation of the end effector using coordinates along orthogonal axes. The Cartesian position and orientation can be computed from the joint positions via the **forward kinematics** function. The motion required to accomplish the desired task is generally specified in Cartesian space. The determination of the joint positions required to achieve the desired end-effector position and orientation is the **inverse kinematics** problem, which may have more than one solution, and a closed-form solution may not be attainable. The desired motion may be specified as point-to-point, in which the end effector moves from one point to another without regard to the path, or it may be specified as a continuous path, in which the end effector follows a desired path between the points. A trajectory planner generally interpolates the desired path and generates a sequence of set points for the controller. The interpolation may be done in joint or Cartesian space.

Some of the robot control schemes in use today include independent joint control [Luh, 1983]; Cartesian-space control [Luh *et al.*, 1980]; and force control strategies such as hybrid position/force control [Raibert and Craig, 1981] and impedance control [Hogan, 1985]. In independent joint control each joint is considered as a separate system and the coupling effects between the links are treated as disturbances to be rejected by the controller. The performance can be enhanced by compensating for the robot nonlinearities and interlink coupling using the method of computed torque or inverse dynamics. In Cartesian-space control the error signals are computed in Cartesian space and the inverse kinematics problem need not be solved. The position control schemes are covered in the following sections. Information on the force control schemes can be

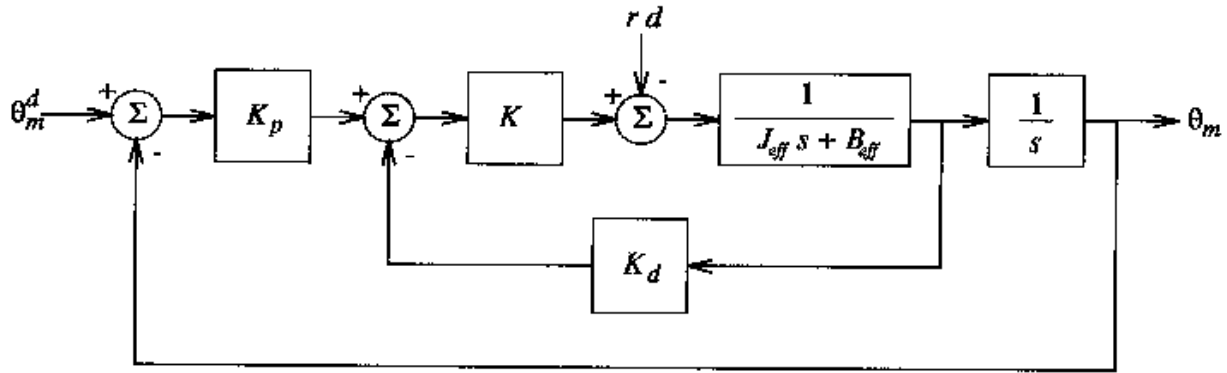

found in the references already cited.

## 158.1 Independent Joint Control

Many industrial robots employ large gear reductions (0.05 to 0.005) that significantly reduce the coupling effects between the links. For slowly varying command inputs, the drive system dominates the dynamics of each joint. Under these conditions each joint can be controlled as an independent system using linear system control techniques. Figure 158.2 depicts a closed-loop system using proportional-derivative (PD) control for a single joint of a robot driven by DC motors.

**Figure 158.2** Closed-loop system for a single robot joint. (Source: Spong, M. W. and Vidyasagar, M. 1989. *Robot Dynamics and Control*, p. 178. John Wiley & Sons, New York. With permission.)

The closed-loop transfer function from input to output is

$$T(s) = \frac{\theta_m(s)}{\theta_m^d(s)} = \frac{K K_p}{J_{\text{eff}} s^2 + (B_{\text{eff}} + K K_d) s + K K_p} \quad (158.1)$$

where  $\theta_m$  is the motor shaft angle, the superscript  $d$  represents a desired quantity,  $K = K_m/R$ ,  $K_m$  is the motor torque constant,  $R$  is the motor armature winding resistance,  $K_p$  is the proportional gain,  $J_{\text{eff}} = J_m + r^2 J_l(\theta)$ ,  $J_m$  is motor and gear inertia,  $r$  is the gear ratio defined by  $r = \theta/\theta_m$ ,  $J_l(\theta)$  is the link inertia,  $\theta$  is the  $n \times 1$  vector of joint positions,  $n$  is the number of links,  $B_{\text{eff}} = B_m + K_b K_m/R$ ,  $B_m$  is the viscous torque constant, and  $K_b$  is the back emf constant. The winding inductance has been ignored because it is frequently small enough such that the time constant of its pole is much smaller than the mechanical time constant.  $J_{\text{eff}}$  depends on the link inertia,  $J_l(\theta)$ , which is dependent on the configuration of the robot links. It is common practice to choose a constant average value for  $J_{\text{eff}}$  considering the variation in link inertia over the robot work space. The range of inertias and gear ratios for the first three links of the PUMA 560 robot are given in Table 158.1. The effect of the gearing is to significantly reduce the contribution of the

link inertia,  $J_l(\theta)$ , to the effective inertia,  $J_{\text{eff}}$ , seen at the joint motor shaft. The characteristic equation for the closed-loop system of Eq. (158.1) is

$$s^2 + \frac{B_{\text{eff}} + K K_d}{J_{\text{eff}}} s + \frac{K K_p}{J_{\text{eff}}} = 0 \quad (158.2)$$

$K_p$  and  $K_d$  can be chosen to achieve the desired damping and natural frequency. It is common practice to choose critical damping in robotic applications to achieve fast response while avoiding overshoot.

The transfer function from the disturbance input to the output is

$$T_d(s) = \frac{\theta(s)}{D(s)} = -\frac{r}{J_{\text{eff}} s^2 + (B_{\text{eff}} + K K_d)s + K K_p} \quad (158.3)$$

where  $d$  is the disturbance input caused by the interlink coupling. For a constant disturbance the steady state error is

$$e_{\text{ss}} = -\frac{r d}{K K_p} \quad (158.4)$$

We see that the error is reduced by the gear reduction and can be made smaller by increasing the proportional gain. For a robot the disturbance in the steady state is due to the effects of gravity on the links. When in motion, the disturbance is dependent on the link velocities and, thus, this control scheme is valid only for slowly time-varying command inputs. In practice there is a limit as to how much  $K_p$  can be increased due to actuator saturation and a necessity to keep the natural frequency well below the structural resonant frequency. An alternative to increasing  $K_p$  to reduce the steady state error is to add integral control to the PD compensator, which reduces the steady state error to zero for constant disturbances.

## 158.2 Method of Computed Torque

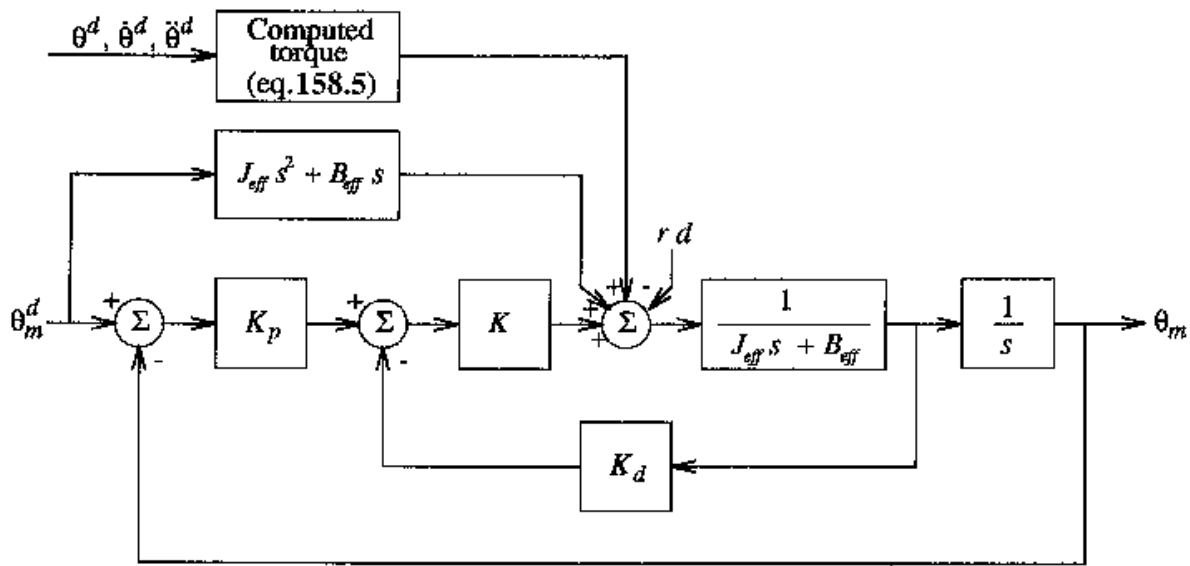

If the robot is a direct-drive type without gear reduction or if the command inputs are not slowly varying, the control scheme of the previous section exhibits poor performance characteristics and

instability may even result. One method of compensating for the effects of the interlink coupling is to use feedforward disturbance cancellation. The disturbance torque is computed from the robot dynamic equation,

$$\tau = D(\theta)\ddot{\theta} + C(\theta, \dot{\theta}) + G(\theta) + F(\dot{\theta}) \quad (158.5)$$

where  $\tau$  is the  $n \times 1$  vector of joint forces/torques,  $D(\theta)$  is the  $n \times n$  inertia matrix,  $C(\theta, \dot{\theta})$  is the  $n \times 1$  vector of Coriolis and centrifugal forces,  $G(\theta)$  is the  $n \times 1$  vector of gravity forces, and  $F(\dot{\theta})$  is the  $n \times 1$  vector of forces due to friction. In the feedforward disturbance cancellation scheme, the right-hand side of Eq. (158.5) is computed using the desired value of the joint variables and injected at the disturbance summing node as shown in Fig. 158.3. If the plant is minimum phase (has no right-half  $s$ -plane zeros), its inverse is also fed forward to achieve tracking of any reference trajectory.

**Figure 158.3** Feedforward computed-torque control.

Another version of computed-torque control, which is known as *inverse dynamics control*, involves setting the control torque to

$$\tau = D(\theta)v + C(\theta, \dot{\theta}) + G(\theta) + F(\dot{\theta}) \quad (158.6)$$

which results in  $\ddot{\theta} = v$ , a double integrator system. The value of  $v$  is now chosen as  $v = \ddot{\theta}^d + K_d(\dot{\theta}^d - \dot{\theta}) + K_p(\theta^d - \theta)$ . This results in the tracking error,  $e = \theta^d - \theta$ , which satisfies

$$\ddot{e} + K_d \dot{e} + K_p e = 0 \quad (158.7)$$

The terms  $K_p$  and  $K_d$  can be chosen for the desired error dynamics (damping and natural frequency). Computed-torque control schemes are computationally expensive due to the complicated nature of Eq. (158.5) and require accurate knowledge of the robot model. They have been successfully implemented using today's powerful and inexpensive computers.

## 158.3 Cartesian-Space Control

The basic concept of Cartesian-space control shown in Fig. 158.4 is that the error signals used in the control algorithm are computed in Cartesian space, obviating the solution of the inverse kinematics. The position and orientation of the robot end effector can be described by a  $3 \times 1$  position vector,  $p$ , and the three orthogonal axes of an imaginary frame attached to the end effector as shown in Fig. 158.5. The axes are known as the normal ( $n$ ), sliding ( $s$ ), and approach ( $a$ ) vectors. The control torque is computed from

$$\tau = D(\theta)\ddot{\theta} + C(\theta, \dot{\theta}) + G(\theta) + F(\dot{\theta}) \quad (158.8)$$

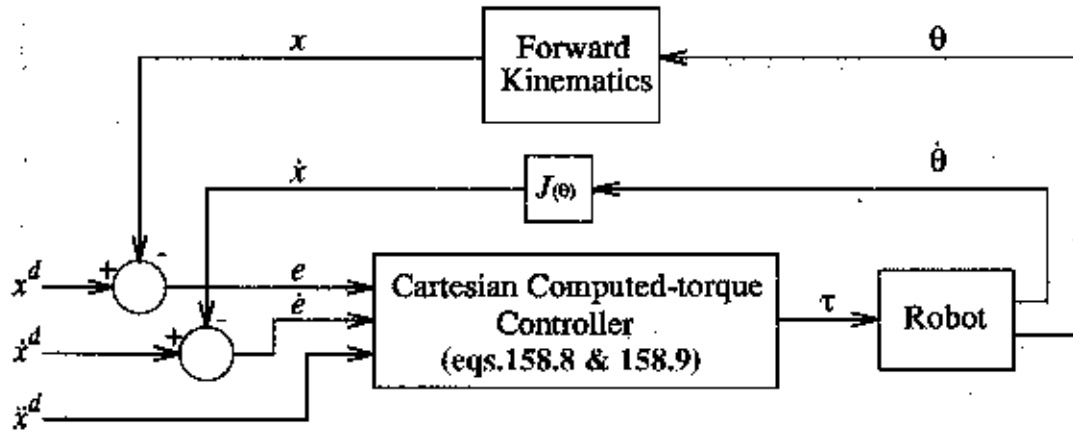

$$\ddot{\theta} = J(\theta)^{-1}[\ddot{x}^d + K_d \dot{e} + K_p e - \dot{J}(\theta, \dot{\theta})\dot{\theta}] \quad (158.9)$$

where  $J(\theta)$  is the manipulator **Jacobian** that maps the joint velocity vector to the Cartesian velocity vector,  $\ddot{x}^d$  is the  $6 \times 1$  desired acceleration vector,  $e = [e_p^T \ e_o^T]^T$ ,  $e_p$  is the  $3 \times 1$  position error vector,  $e_o$  is the  $3 \times 1$  orientation error vector,  $K_d$  is the  $6 \times 6$  positive-definite matrix of velocity gains, and  $K_p$  is the  $6 \times 6$  positive-definite matrix of position gains. The actual position and orientation of the end effector is computed from the joint positions via the forward kinematics. The position error is computed from  $e_p = p^d - p$  and, for small error, the orientation error is computed from  $e_o = \frac{1}{2}[n \times n^d + s \times s^d + a \times a^d]$ . The control law of Eqs. (158.8) and (158.9) results in the Cartesian error equation,

$$\ddot{e} + K_d \dot{e} + K_p e = 0 \quad (158.10)$$

The gain matrices  $K_d$  and  $K_p$  can be chosen to be diagonal to achieve the desired error dynamics along each Cartesian direction.

**Figure 158.4** Cartesian computed-torque controller.

**Figure 158.5** End-effector position and orientation.

The Cartesian-space controller has the disadvantage that the inverse of the Jacobian is required, which does not exist at **singular configurations**. The planned trajectory must avoid singularities, or alternative methods such as the SR pseudoinverse [Nakamura, 1991] must be used to compute the Jacobian inverse.

This photograph of JASON was taken in 1993 in Ireland on an expedition to explore the wreck of the Lusitania. JASON has also excavated an ancient shipwreck site 2000 meters down in the Mediterranean (1989) and explored the wrecks of two 1812 warships in Lake Ontario (1990), in addition to many mapping missions for science and the U.S. Navy. (Photo courtesy of D. Mindell.)

#### CONTROL SYSTEM FOR JASON

*D. Mindell, Massachusetts Institute of Technology*

JASON is a remotely operated vehicle (ROV) specifically designed for deep-ocean exploration, built and operated by the Deep Submergence Laboratory of the Woods Hole Oceanographic Institution in Woods Hole, Mass. All of its components are qualified to operate at depths up to 6000 m, which encompasses 95% of the ocean floor. The vehicle has worked that deep, although it typically operates in the 2000–3000 m range. The vehicle connects through a short tether (~50–100 m) to MEDEA. MEDEA, a heavy steel cage, connects through a long, armored cable back to a surface ship, effectively decoupling JASON's tether from ship and cable motion. This arrangement gives the ROV freedom to maneuver and explore. MEDEA also carries some lights and a video camera to enable operators to view JASON from above while working. The cable has three power conductors, for 1800 V at 400 Hz AC transmitted from a power supply on the surface

(originally designed as an auxiliary supply for jet aircraft on the ground). Also in the cable are three single-mode optical fibers, each multiplexed for two channels. Two of the fibers are dedicated to FM video uplink from the vehicle to the surface, providing four video channels, and the other fiber is used for data transmission (500 Mbits/s in both directions).

JASON's control system consists of a network of parallel processors running on the surface ship, connected through the fiber-optic tether to a similar network running on the vehicle itself. On the surface, the control system connects to data logging devices. GPS navigation, the dynamic positioning system of the ship, and the pilot interface. The subsea portion of the control system performs all vehicle functions, and enables the pilot on the surface to teleoperate the vehicle using feedback from video and sensors and to operate JASON's remote manipulator arm. JASON's control system can also operate closed-loop, based on high-precision navigation data. An acoustic navigation system, called EXACT, uses a network of battery-powered transponders on the seabed to locate JASON with an accuracy of 1 cm<sup>3</sup> within a 100 m range. JASON's control system uses these data as feedback to automatically hover or run precision surveys. In conjunction with data from a scanning sonar, for example, precise tracklines produce the data necessary to make 3-D computer models of structures on the seafloor. JASON has performed such surveys on the wreck of the Lusitania, two ships from the war of 1812, and hydrothermal vents ("black smokers") in the Pacific Ocean and the Sea of Cortez.

## Defining Terms

**Cartesian or task space:** The set of vectors describing the position and orientation of the end effector using coordinates along orthogonal axes. The position is specified by a  $3 \times 1$  vector of the coordinates of the end-effector frame origin. The orientation is specified by the  $3 \times 1$  normal, sliding, and approach vectors describing the directions of the orthogonal axes of the frame. Alternately, the orientation may be described by Euler angles, roll/pitch/yaw angles, or axis/angle representation.

**Forward kinematics:** The function that maps the position of the joints to the Cartesian position and orientation of the end effector. It maps the joint space of the manipulator to Cartesian space.

**Inverse kinematics:** The function that maps the Cartesian position and orientation of the end effector to the joint positions. It is generally a one-to-many mapping, and a closed-form solution may not always be possible.

**Jacobian:** The function that maps the joint velocity vector to the Cartesian translational and angular velocity vector of the end effector:  $\dot{x} = J(\theta)\dot{\theta}$ .

**Singular configuration:** A configuration of the manipulator in which the manipulator Jacobian loses full rank. It represents configurations from which certain directions of motion are not possible or when two or more joint axes line up and there is an infinity of solutions to the inverse kinematics problem.

## State Variable Feedback

---

159.1 Linear State Space Control Systems

159.2 Controllability and Observability

159.3 Eigenvalue Placement

159.4 Observer Design

**Thomas L. Vincent**

*University of Arizona*

The fundamental concept in control system design deals with creating a **feedback loop** between the **output** and the **input** of a dynamical system. This is done to improve the stability characteristics of the system. State variable feedback is associated with the idea of using every **state variable** in the feedback loop. State variable feedback is used in both nonlinear and linear systems. However, it is only with linear systems that a relatively complete theory has been worked out, with some of the results given in this chapter. The advantage of using state variable feedback for linear control system design is in its simplicity. However, in order to use state variable feedback, every state variable must be either measured or estimated. Since measuring every state variable is impractical for most control applications, a state estimator must usually be included as a part of the total state variable feedback control system.

### 159.1 Linear State Space Control Systems

---

A large class of control systems are either given by or approximated by a linear state space model of the form

$$\dot{\mathbf{x}} = \mathbf{A}\mathbf{x} + \mathbf{B}\mathbf{u} \quad (159.1)$$

$$\mathbf{y} = \mathbf{C}\mathbf{x} + \mathbf{D}\mathbf{u} \quad (159.2)$$

where the dot denotes differentiation with respect to time,  $\mathbf{x}$  is an  $N_x \times 1$  dimensional state vector,  $\mathbf{u}$  is an  $N_u \times 1$  dimensional control vector,  $\mathbf{y}$  is an  $N_y \times 1$  dimensional output vector,  $\mathbf{A}$  is a square  $N_x \times N_x$  matrix,  $\mathbf{B}$  is  $N_x \times N_u$ ,  $\mathbf{C}$  is  $N_y \times N_x$ , and  $\mathbf{D}$  is  $N_y \times N_u$ . The state vector

$$\mathbf{x} = [x_1 \cdots x_{N_x}]^T \quad (159.3)$$

where  $()^T$  denotes transpose, is defined by the solution to the differential equation (159.1). The

control vector

$$\mathbf{u} = [u_1 \cdots u_{N_u}]^T \quad (159.4)$$

represents all control inputs to the system. Control inputs include both **open-loop command inputs** external to the system and **closed-loop control inputs** internal to the system. Control is ultimately transmitted to the system through the use of actuators that may or may not be modeled in Eq. (159.1). It follows from Eq. (159.1) that the state of the system cannot be determined until all inputs, along with initial conditions for the state, have been specified. The output vector

$$\mathbf{y} = [y_1 \cdots y_{N_y}]^T \quad (159.5)$$

represents all of the system quantities measured by means of sensors. The sensor output may be of the general form of Eq. (159.2), where it is a function of both the state and control inputs (e.g., accelerometer) or it may be simply one or more of the state variables (e.g., position sensor, tachometer). The control system design problem is to determine an automatic control algorithm such that the relationship between a command input  $r(t)$  and the output  $y(t)$  yields acceptable performance in terms of tracking, stability, uncertain inputs, and so forth. These qualitative performance criteria are determined by the controlled system eigenvalues.

## 159.2 Controllability and Observability

---

The concepts of controllability and observability are fundamental to state space design. If a system is controllable, then it will always be possible, using state variable feedback, to design a stable controlled system. In fact, the controlled systems eigenvalues may be arbitrarily placed. If a system is observable, then it will always be possible to design an estimator for the state.

The system in Eq. (159.1) is controllable if for every initial state  $\mathbf{x}(0)$  there exists a control  $\mathbf{u}(t), t \in [0, T]$ , where  $T$  is some finite time interval, that will drive the system to any other point in state space. The system in Eqs. (159.1) and (159.2) is observable if, given a control  $\mathbf{u}(t), t \in [0, T]$ , the initial state  $\mathbf{x}(0)$  can be determined from the observation history  $\mathbf{y}(t), t \in [0, T]$ .

Controllability and observability for linear systems in the form of Eqs. (159.1) and (159.2) may be checked using the Kalman controllability and observability criteria. The Kalman controllability criterion is that the system in Eq. (159.1) is controllable if and only if

$$\text{rank} [\mathbf{P}] = N_x \quad (159.6)$$

where  $\mathbf{P}$  is the controllability matrix

$$\mathbf{P} = [\mathbf{B}, \mathbf{AB}, \cdots, \mathbf{A}^{N_x-1} \mathbf{B}] \quad (159.7)$$

The Kalman observability criterion is that the system in Eqs. (159.1) and (159.2) is observable if

and only if

$$\text{rank } [\mathbf{Q}] = N_x \quad (159.8)$$

where  $\mathbf{Q}$  is the observability matrix

$$\mathbf{Q} = \begin{bmatrix} \mathbf{C} \\ \mathbf{CA} \\ \mathbf{CA}^2 \\ \vdots \\ \mathbf{CA}^{N_x-1} \end{bmatrix} \quad (159.9)$$

State variable feedback design requires that both the controllability and observability criteria be satisfied, which will be assumed in what follows. State space design may be broken into two parts, eigenvalue placement, assuming full state information is available, and observer design to supply any missing state information.

### 159.3 Eigenvalue Placement

---

Assume that every component of the state  $\mathbf{x}$  is measured—that is,  $\mathbf{C} = \mathbf{I}$  and  $\mathbf{D} = 0$  so that  $\mathbf{y} = \mathbf{x}$ . Given that the desired controlled system eigenvalues are known, the design problem is reduced to finding an  $N_u \times N_x$  feedback gain matrix  $\mathbf{K}$  such that Eq. (159.1) under state variable feedback of the form

$$\mathbf{u} = \mathbf{F}\mathbf{r}(t) - \mathbf{K}\mathbf{x}(t) \quad (159.10)$$

will have the prescribed eigenvalues. Here,  $\mathbf{r}(t)$  is an  $N_x \times 1$  vector of command inputs and  $\mathbf{F}$  is an  $N_x \times N_r$  input matrix. The  $\mathbf{F}$  matrix will in general be required, since the dimension of the command inputs may not equal the dimension of the control vector. It also provides for scaling of the command input. Substituting Eq. (159.10) into Eq. (159.1) yields

$$\dot{\mathbf{x}} = \hat{\mathbf{A}}\mathbf{x} + \hat{\mathbf{B}}\mathbf{r} \quad (159.11)$$

where

$$\hat{\mathbf{A}} = \mathbf{A} - \mathbf{BK} \quad (159.12)$$

$$\hat{\mathbf{B}} = \mathbf{BF} \quad (159.13)$$

The controlled system of Eq. (159.11) is of the same form as the original system in Eq. (159.1), except the matrix  $\hat{\mathbf{A}}$  now depends on the matrix of feedback gains  $\mathbf{K}$ , and the control input,  $\mathbf{u}$ , is now the command input  $\mathbf{r}$ . For a constant command input the equilibrium solutions to Eq. (159.11) depend on both  $\mathbf{F}$  and  $\mathbf{K}$ . However,  $\mathbf{K}$  alone affects the eigenvalues of the controlled system. If Eq.

(159.1) is completely controllable, then any desired set of eigenvalues for  $\bar{A}$  can be obtained through an appropriate choice for  $\mathbf{K}$  [Davison, 1968; Wonham, 1967].

For single-input systems ( $u$  is a scalar) of low dimensions, determining  $\mathbf{K}$  for direct eigenvalue placement is easy to do. For example, consider a second-order system of the form of Eq. (159.1) with

$$A = \begin{bmatrix} 0 & 1 \\ a_1 & a_2 \end{bmatrix} \quad B = \begin{bmatrix} 0 \\ b \end{bmatrix} \quad (159.14)$$

This system satisfies Eq. (159.6) so that state space design is possible. Under state variable feedback,

$$\bar{A} = \begin{bmatrix} 0 & 1 \\ a_1 - bk_1 & a_2 - bk_2 \end{bmatrix} \quad (159.15)$$

which has the characteristic equation

$$\lambda^2 + (bk_2 - a_2)\lambda + (bk_1 - a_1) = 0 \quad (159.16)$$

This system can now be made to behave like a second-order system with eigenvalues  $\bar{\lambda}_1$  and  $\bar{\lambda}_2$  satisfying the characteristic equation

$$(\lambda - \bar{\lambda}_1)(\lambda - \bar{\lambda}_2) = \lambda^2 + 2\zeta\omega_n\lambda + \omega_n^2 = 0 \quad (159.17)$$

by matching coefficients to yield

$$k_1 = (a_1 + \omega_n^2)/b; \quad k_2 = (a_2 + 2\zeta\omega_n)/b \quad (159.18)$$

This procedure is also applicable when  $\mathbf{u}$  is a vector, but it is complicated by the fact that the gain matrix  $\mathbf{K}$  is not unique. However, a general procedure to handle this situation is available [Wonham, 1985]. The procedure can also be readily adapted for numerical solution so that higher dimensional problems can be handled as well.

Unless one is certain about what eigenvalues to use, the question of where to place the controlled system eigenvalues remains a fundamental design problem. There are methods available for handling this aspect of state variable feedback design as well. Some of the more commonly used methods are optimal (LQ) design [Bryson and Ho, 1975] and robust control design [Green and Limebeer, 1994]. These methods focus on other system performance criteria for determining the feedback gain matrix  $\mathbf{K}$ , which, in turn, indirectly determine the controlled system eigenvalues. Software is available, based on these methods, for doing control design on a PC [Shahian and Hassul, 1993].

## 159.4 Observer Design

---

Even if every component of the state vector  $\mathbf{x}$  is not directly measured, it is possible to build a device called an *observer* [Luenberger, 1971] that will approximate  $\mathbf{x}$ . An observer that reconstructs the entire state vector is called an *identity observer*. One that only reconstructs states not directly measured is called a *reduced-order observer*. Identity observers are of a simpler form.

An observer uses the system model with an additional output feedback term to generate an estimate for the state. If we let  $\hat{\mathbf{x}}$  denote the estimate of  $\mathbf{x}$ , then an identity observer is obtained from the equations

$$\dot{\hat{\mathbf{x}}} = \mathbf{A}\hat{\mathbf{x}} + \mathbf{B}u - \mathbf{G}[\hat{\mathbf{y}} - y] \quad (159.19)$$

where  $\hat{\mathbf{x}}(0) = \mathbf{0}$ ,  $\mathbf{G}$  is an  $N_x \times N_y$  matrix to be determined, and

$$\hat{\mathbf{y}} = \mathbf{C}\hat{\mathbf{x}} + \mathbf{D}u \quad (159.20)$$

is the predicted measurement in accordance with Eq. (159.2). The structure of the state estimator from Eqs. (159.19) and (159.20) is the same as a Kalman filter [Kalman, 1960], which is used for state estimation in the presence of Gaussian random noise inputs.

Substituting (159.20) into (159.19) and rearranging terms yields the identity observer

$$\dot{\hat{\mathbf{x}}} = [\mathbf{A} - \mathbf{GC}]\hat{\mathbf{x}} + [\mathbf{B} - \mathbf{GD}]u + \mathbf{G}y \quad (159.21)$$

The components of the  $\mathbf{G}$  matrix are chosen so that the error equation

$$\dot{\mathbf{e}} = \hat{\mathbf{x}} - \mathbf{x} = [\mathbf{A} - \mathbf{GC}]\mathbf{e} \quad (159.22)$$

will be stable. The **return time** of the error equation should be chosen so that it is faster than the return time of the controlled system. The stability properties of the error equation are completely under the designer's control, provided that the system in Eqs. (159.1) and (159.2) is observable. For controllable and observable linear systems, observers do not change the closed-loop eigenvalues of the controlled system. Rather, they simply adjoin their own eigenvalues. That is, the eigenvalues for the controlled system using an identity observer are those associated with  $[\mathbf{A} - \mathbf{BK}]$  and  $[\mathbf{A} - \mathbf{GC}]$ , respectively.

As an example, consider the second-order system given by Eq. (159.14), in which the output is the first state variable  $x_1$ , that is,

$$\mathbf{C} = [1 \quad 0] \quad \mathbf{D} = 0 \quad (159.23)$$

The observability criterion of Eq. (159.8) is satisfied by this system so that an observer can be built. In this case

$$A - GC = \begin{bmatrix} -g_1 & 1 \\ a_1 - g_2 & a_2 \end{bmatrix} \quad (159.24)$$

which has the characteristic equation

$$\lambda^2 + (g_1 - a_2)\lambda + (g_2 - a_2g_1 - a_1) = 0 \quad (159.25)$$

By choosing the constants  $g_1$  and  $g_2$ , the observer can now be made to behave like a second-order system with eigenvalues  $\hat{\lambda}_1$  and  $\hat{\lambda}_2$  satisfying the characteristic equation

$$(\lambda - \hat{\lambda}_1)(\lambda - \hat{\lambda}_2) = \lambda^2 + 2\hat{\zeta}\hat{\omega}_n\lambda + \hat{\omega}_n^2 = 0 \quad (159.26)$$

Equating coefficients between Eqs. (159.25) and (159.26) yields

$$g_1 = a_2 + 2\hat{\zeta}\hat{\omega}_n; \quad g_2 = a_1 + a_2g_1 + \hat{\omega}_n^2 \quad (159.27)$$

The observer in this case is of the form

$$\dot{\hat{x}}_1 = \hat{x}_2 + g_1(y - \hat{x}_1) \quad (159.28)$$

$$\dot{\hat{x}}_2 = a_1\hat{x}_1 + a_2\hat{x}_2 + g_2(y - \hat{x}_1) + bu \quad (159.29)$$

These equations must be solved on-line to yield  $\hat{x}_1$  and  $\hat{x}_2$ . The resulting controller is

$$u = r - k_1\hat{x}_1 - k_2\hat{x}_2 \quad (159.30)$$

In this case the actual measurement  $y = x_1$  could be used in Eq. (159.30) instead of  $\hat{x}_1$ . However, if the measurement of  $y$  contains noise, this noise can be filtered through the observer by using the full state estimate  $\hat{x}$  as used in Eq. (159.30).

The observer differential equations may be solved on-line by either digital or analog methods. The initial conditions for solving these equations will generally not be known. However, in most situations, this should not present difficulties with a properly designed observer. Any error resulting from setting all the initial conditions equal to zero will rapidly tend to zero according to the error equation.

## Defining Terms

**Closed-loop control inputs:** Inputs to a control system, given as a function of the output, that are determined by an automatic control algorithm within the system (usually computed by an analog or digital device).

**Feedback loop:** Any connection between the input and the output of a dynamical system.

**Input:** The inputs to a dynamical system are quantities that can affect the evolution of the state of

the system.

**Open-loop command inputs:** Inputs to a control system, given as a function of time, that are initiated by a human operator or some other external device used to specify a desired output.

**Output:** Those functions of the state and control, possibly the states themselves, that can be measured.

**Return time:** For asymptotically stable systems, with eigenvalues  $\lambda_i$ , the return time is defined by  $T = 1/\min |\operatorname{Re}(\lambda_i)|$ ,  $i = 1, \dots, N_x$  and the eigenvalue(s) corresponding to  $T$  is called the *dominant eigenvalue(s)*. The dominate eigenvalue(s) corresponds to the slowest time constant in the system.

**State variables:** Those variables that identify the state of a system. The state of a dynamical system are those dynamical components of a system that completely identify it at any moment in time.

DURING THE PAST DECADE, competition on a worldwide scale has intensified, with every country attempting to increase its share in the world economy. As a result, the manufacturing

processes have to adapt frequently to changing market demands for products, and innovations in design have to be accommodated. Competition also requires improved quality, cost reduction, improved management efficiency, and flexibility. All of these requirements are part and parcel of modern engineering.

It is commonly accepted engineering wisdom that new ideas are useless if they cannot be implemented, and outstanding engineering designs are worthless if they cannot be produced. The engineer responsible for conceiving and implementing production methods and for creating useful products from ideas and designs is the key to success in competition. The manufacturing engineer must work with severe constraints in terms of the design, the cost, and the time available to create a new product. This section covers the main ingredients required in the field of manufacturing, including quality control, flexible manufacturing, management, design, materials processing, and ergonomics. In addition, the section covers topics such as agricultural engineering and reliability. These are enormously broad and important topics, and the coverage in a handbook is necessarily limited. However, the reader will find the material useful in gaining an understanding of the various elements of manufacturing and can consult the references at the end of the chapters for more detailed and in-depth information.

## Types of Manufacturing

160.1 Job-Shop and Batch Production

160.2 Mass Production

160.3 Continuous Production

160.4 Mixtures and Gray Areas

160.5 Capital Investment, Automation, Advanced Technology, Skills, and Layout

**Richard J. Schonberger**

*University of Washington*

Although there are many ways to categorize manufacturing, three general categories stand out. These three (which probably have emerged from production planning and control lines of thought) are:

1. **Job-shop production.** A job shop produces in small lots or batches.
2. **Mass production.** Mass production involves machines or assembly lines that manufacture discrete units repetitively.
3. **Continuous production.** The **process industries** produce in a continuous flow.

Primary differences among the three types center on output volume and variety and process flexibility. [Table 160.1](#) matches these characteristics with the types of manufacturing and gives examples of each type. The following discussion begins by elaborating on [Table 160.1](#). Next are comments on hybrid and uncertain types of manufacturing. Finally, five secondary characteristics of the three manufacturing types are presented.

**Table 160.1** Types of Manufacturing—Characteristics and Examples

Volume	Very low	High	Highest
Variety	Highest	Low	Lowest
Flexibility	Highest	Low	Lowest
Job-shop production	Tool and die making Casting (foundry) Baking (bakery)		
Mass production	Auto assembly Bottling Apparel manufacturing		
Continuous production	Paper milling Refining Extrusion		

## 160.1 Job-Shop and Batch Production

---

As [Table 160.1](#) shows, job-shop manufacturing is very low in volume but is highest in output variety and process flexibility. In this mode, the processes—a set of resources including labor and equipment—are reset intermittently to make a variety of products. (Product variety requires flexibility to frequently reset the process.)

In tool and die making, the first example, the volume is generally one unit—for example, a single die set or mold. Since every job is different, output variety is at a maximum, and operators continually reset the equipment for the next job.

Casting in a foundry has the same characteristics, except that the volume is sometimes more than one. That is, a given job order may be to cast one, five, ten, or more pieces. The multipiece jobs are sometimes called lots or **batches**.

A bakery makes a variety of products, each requiring a new series of steps to set up the process—for example, mixing and baking a batch of sourdough bread, followed by a batch of cinnamon rolls.

## 160.2 Mass Production

---

Second in [Table 160.1](#) is mass production. Output volume, in discrete units, is high. Product variety is low, entailing low flexibility to reset the process.

Mass production of automobiles is an example. A typical automobile plant will assemble two or three hundred thousand cars a year. In some plants just one model is made per assembly line; variety is low (except for option packages). In other plants assembly lines produce mixed models. Still, this is considered mass production since assembly continues without interruption for model changes.

In bottling, volumes are much higher, sometimes in the millions per year. Changing from one bottled product to another requires a line stoppage, but between **changeovers** production volumes are high (e.g., thousands). Flexibility, such as changing from small to large bottles, is low; more commonly, large and small bottles are filled on different lines.

Similarly, mass production of apparel can employ production lines, with stoppages for pattern changes. More conventionally, the industry has used a very different version of mass production: Cutters, sewers, and others in separate departments each work independently, and material handlers move components from department to department to completion. Thus, existence of an assembly line or production line is not a necessary characteristic of mass production.

## 160.3 Continuous Production

---

Products that flow—liquids, gases, powders, grains, slurries—are continuously produced, the third type in [Table 160.1](#). In continuous process plants, product volumes are very high (relative to, for

example, a job-shop method of making the same product). Because of designed-in process limitations (pumps, pipes, valves, etc.) product variety and process flexibility are very low.

In a paper mill a meshed belt begins pulp on its journey through a high-speed multistage paper-making machine. The last stage puts the paper on reels holding thousands of linear meters. Since a major product changeover can take hours, plants often limit themselves to incremental product changes. Special-purpose equipment design also poses limitations. For example, a tissue machine cannot produce newsprint, and a newsprint machine cannot produce stationery. Thus, in paper making, flexibility and product variety for a given machine are very low.

Whereas a paper mill produces a solid product, a refinery keeps the substance in a liquid (or sometimes gaseous) state. Continuous refining of fats, for example, involves centrifuging to remove undesirable properties to yield industrial or food oils. As in paper making, specialized equipment design and lengthy product changeovers (including cleaning of pipes, tanks, and vessels) limit process flexibility; product volumes between changeovers are very high, sometimes filling multiple massive tanks in a tank farm.

Extrusion, the third example of continuous processing in [Table 160.1](#), yields such products as polyvinyl chloride (PVC) pipe, polyethylene film, and reels of wire. High process speeds produce high product volumes, such as multiple racks of pipe, rolls of film, or reels of wire per day. Stoppages for changing extrusion heads and many other adjustments limit process flexibility and lead to long production runs between changeovers. Equipment limitations (e.g., physical dimensions of equipment components) keep product variety low.

## 160.4 Mixtures and Gray Areas

---

Many plants contain a mixture of manufacturing types. A prominent example can be found in the process industries, where production usually is only partially continuous. Batch mixing of pulp, fats, or plastic granules precedes continuous paper making, refining of oils, and extrusion of pipe. Further processing may be in the job-shop mode: slitting and length-cutting paper to customer order, secondary mixing and drumming of basic oils to order, and length-cutting and packing of pipe to order.

Mixed production also often occurs in mass production factories. An assembly line (e.g., assembling cars or trucks) may be fed by parts, such as axles, machined in the job-shop mode from castings that are also job-shop produced. Uniform mass-made products (e.g., molded plastic hard hats) may go to storage where they await a customer order for final finishing (e.g., decals) in the job-shop mode. An apparel plant may mass-produce sportswear on one hand and produce custom uniforms for professional sports figures in the job-shop mode on the other.

More than one type of manufacturing in the same plant requires more than one type of production planning, scheduling, and production. The added complexity in management may be offset, however, by demand-side advantages of offering a fuller range of products.

Sometimes, a manufacturing process does not fit neatly into one of the three basic categories. One gray area occurs between mass production and continuous production. Some very small

products—screws, nuts, paper clips, toothpicks—are made in discrete units. But because of small size, high volumes, and uniformity of output, production may be scheduled and controlled not in discrete units but by volume, thus approximating continuous manufacturing. Production of cookies, crackers, potato chips, and candy resembles continuous forming or extrusion of sheet stock on wide belts, except that the process includes die-cutting or other separation into discrete units—like mass production. Link sausages are physically continuous, but links are countable in whole units.

Another common gray area is between mass and job-shop production. A notable example is high-volume production of highly configured products made to order. Products made for industrial uses—such as specialty motors, pumps, hydraulics, controllers, test equipment, and work tables—are usually made in volumes that would qualify as mass production, except that end-product variety is high, not low.

These types of manufacturing with unclear categories do not necessarily create extra complexity in production planning and control. The difficulty and ambiguity are mainly terminological.

## **160.5 Capital Investment, Automation, Advanced Technology, Skills, and Layout**

---

The three characteristics used to categorize manufacturing—volume, variety, and flexibility—are dominant but not exhaustive. To some extent, the manufacturing categories also differ with respect to capital investment, automation, technology, skills, and layout.

Typically, continuous production is highly capital-intensive, whereas mass production is often labor-intensive. The trend toward automated, robotic assembly, however, is more capital-intensive and less labor-intensive, which erodes the distinction. Job-shop production on conventional machines is intermediate as to capital investment and labor intensiveness. However, computer numerically controlled (CNC) machines and related advanced technology in the job shop erodes this distinction as well.

As technology distinctions blur, so do skill levels of factory operatives. In conventional high-volume assembly, skill levels are relatively low, whereas those of machine operators in job shops—such as machinists and welders—tend to be high. But in automated assembly, skill levels of employees tending the production lines elevate toward technician levels—more like machinists and welders. In continuous production skill levels range widely—from low-skilled carton handlers and magazine fillers to highly skilled process technicians and troubleshooters.

Layout of equipment and related resources is also becoming less of a distinction than it once was. The classical job shop is laid out by type of equipment: all milling machines in one area, all grinding machines in another. Mass and continuous production have been laid out by the way the product flows: serially and linearly. Many job shops, however, have been converted to cellular layouts—groupings of diverse machines that produce a family of similar products. In most work cells the flow pattern is serial from machine to machine, but the shape of the cell is not linear; it is U-shaped or, for some larger cells, serpentine. Compact U and serpentine shapes are thought to

provide advantages in teamwork, material handling, and labor flexibility.

To some degree, such thinking has carried over to mass production. That is, the trend is to lay out assembly and production lines in U and serpentine shapes instead of straight lines, which was the nearly universal practice in the past. In continuous production of fluids the tendency has always been toward compact facilities interconnected by serpentine networks of pipes. Continuous production of solid and semisolid products (wide sheets, extrusions, etc.), on the other hand, generally must move in straight lines, in view of the technical difficulties in making direction changes.

## Defining Terms

**Batch:** A quantity (a lot) of a single item.

**Changeover (setup):** Setting up or resetting a process (equipment) for a new product or batch.

**Continuous production:** Perpetual production of goods that flow and are measured by area or volume; usually very high in product volume, very low in product variety, and very low in process flexibility.

**Job-shop production:** Intermittent production with frequent resetting of the process for a different product or batch; usually low in product volume, high in product variety, and high in process flexibility.

**Mass production:** Repetitive production of discrete units on an assembly line or production line; usually high in product volume, low in product variety, and low in process flexibility.

**Process:** A set of resources and procedures that produces a definable product (or service).

**Process industry:** Manufacturing sector involved in continuous production.

## Quality

---

### 161.1 Measurement

Normal Distribution

### 161.2 Statistical Quality Control

Control Charts for Variables • Control Charts for Attributes

### 161.3 Tolerances and Capability

**Matthew P. Stephens**

*Purdue University*

**Joseph F. Kmec**

*Purdue University*

Although no universally accepted definition of **quality** exists, in its broadest sense quality has been described as "conformance to requirements," "freedom from deficiencies," or "the degree of excellence which a thing possesses." Taken within the context of the manufacturing enterprise, quality—or, more specifically, manufacturing quality—shall be defined as "conformance to requirements." This chapter focuses on the evaluation of product quality, with particular emphasis directed at statistical methods used in the measurement, control, and tolerances needed to achieve the desired quality. Factors that define product quality are ultimately determined by the customer and include such traits as reliability, affordability or cost, availability, user friendliness, and ease of repair and disposal. To ensure that quality goals are met, manufacturing firms have initiated a variety of measures that go beyond traditional product inspection and record keeping, which, by and large, were the mainstays of quality control departments for decades. One such initiative is total quality management (TQM) [Saylor, 1992], which focuses on the customer, both inside and outside the firm. It consists of a disciplined approach using quantitative methods to continuously improve all functions within an organization. Another initiative is registration under the ISO 9000 series [Lamprecht, 1993], which provides a basis for U.S. manufacturing firms to qualify their finished products and processes to specified requirements. More recently, the U.S. government has formally recognized outstanding firms through the coveted Malcolm Baldrige Award [ASQC, 1994] for top quality among U.S. manufacturing companies. One of the stipulations of the award is that recipient companies share information on successful quality strategies with their manufacturing counterparts.

## 161.1 Measurement

---

The inherent nature of the manufacturing process is variation. Variation is present due to any one or a combination of factors including materials, equipment, operators, or the environment. Controlling variation is an essential step in realizing product quality. To successfully control variation, manufacturing firms rely on the measurement of carefully chosen parameters. Because measurement of the entire population of products or components is seldom possible or desirable, **samples** from the **population** are chosen. The extent to which sample data represent the population depends largely on such items as sample size, method of sampling, and time-dependent variations.

Measured data from samples taken during a manufacturing process can be plotted in order to determine the shape of the **frequency distribution**. The frequency distribution can give a visual clue to the process average and dispersion. The latter is referred to as **standard deviation**. [Figure 161.1](#) shows a frequency distribution plot of 40 coded pin lengths expressed in thousands of an inch above 1 inch. Thus the coded length 6 represents an actual length of 1.006 in. For the data shown, average coded pin length is 8.475 and standard deviation is 1.585.

**Figure 161.1** Coded pin lengths.

## Normal Distribution

Although there is an infinite variety of frequency distributions, the variation of measured parameters typically found in the manufacturing industry follows that of the normal curve. The normal distribution is a continuous bell-shaped plot of frequency versus some parameter of interest and is an extension of a histogram whose basis is a large population of data points. [Figure 161.2](#) shows a normal distribution plot superimposed on a histogram. Some important properties of the normal distribution curve are:

1. The distribution is symmetrical about the population mean  $\mu$ .
2. The curve can be described by a specific mathematical function of population mean  $\mu$  and population standard deviation  $\sigma$ .

An important relationship exists between standard deviation and area under the normal distribution curve. Such a relationship is shown in [Fig. 161.3](#) and may be interpreted as follows: 68.26% of the readings (or area under the curve) will be between  $\pm 1\sigma$  limits, 95.46% of the readings will be between  $\pm 2\sigma$  limits, and 99.73% of the readings will be between  $\pm 3\sigma$  limits. The significance of this relationship is that the standard deviation can be used to calculate the percentage of the population that falls between any two given values in the distribution.

**Figure 161.2** Normal distribution curve.

**Figure 161.3** Percentages under the normal curve.

## 161.2 Statistical Quality Control

---

Statistical quality control (SQC) deals with collection, analysis, and interpretation of data to monitor a particular manufacturing or service process and ensure that the process remains within its capacity. In order to understand process capability, it is necessary to realize that variation is a natural phenomenon that will occur in any process. Parts will appear identical only due to the limitation of the inspection or measurement instrument. The sources of these variations may be the material, process, operator, time of the operation, or any other significant variables. When these factors are kept constant, the minor variations inherent in the process are called *natural* (or *chance*) *variations*, as opposed to variations due to **assignable causes**.

Control charts are utilized to determine when a given process variation is within the expected or natural limits. When the magnitude of variation exceeds these predetermined limits, the process is said to be *out of control*. The causes for out-of-control conditions are investigated and the process is brought back in control. Control charts or the control limits for the natural or chance-cause variations are constructed based on the relationship between the normal distribution and the standard deviation of the distribution. The property of normal distribution and its relationship to the standard deviation of the distribution was discussed in **Chapter 160**. As stated earlier, since approximately 99.73% of a normal distribution is expected to fall between  $\pm 3\sigma$  of the distribution, control limits are established at  $\bar{X} \pm 3\sigma$  for the process. Therefore, any sample taken from the process is expected to fall between the control limits or the  $\bar{X} \pm 3\sigma$  of the process 99.73% of the

time. Any sample not within these limits is assumed to indicate an out-of-control condition for which an assignable cause is suspected.

Control charts can be divided into two major categories: control charts for variables (measurable quality characteristics, i.e., dimension, weight, hardness, etc.) and control charts for attributes (those quality characteristics not easily measurable and therefore classified as conforming or not conforming, good or bad, etc.).

## Control Charts for Variables

The most common charts used for variables are the  $\bar{X}$  and  $R$  charts. The charts are used as a pair for a given quality characteristic. In order to construct control charts for variables, the following steps may be followed:

1. Define the quality characteristic that is of interest. Control charts for variables deal with only one quality characteristic; therefore, if multiple properties of the product of the process are to be monitored, multiple charts should be constructed.
2. Determine the sample (also called the *subgroup*) size. When using control charts, individual measurements or observations are not plotted, but, rather, sample averages are utilized. One major reason is the nature of the statistics and their underlying assumptions. Normal statistics, as the term implies, assumes a normal distribution of the observations. Although many phenomena may be normally distributed, this is not true of all distributions. A major statistical theory called the *central limit theorem* states that the distribution of sample averages will tend toward normality as the sample size increases, regardless of the shape of the parent population. Therefore, plotting sample averages ensures a reasonable normal distribution so that the underlying assumption of normality of the applied statistics is met.

The sample size (two or larger) is a function of cost and other considerations, such as ease of measurement, whether the test is destructive, and the required sensitivity of the control charts. As the sample size increases, the standard deviation decreases; therefore, the control limits will become tighter and more sensitive to process variation.

3. For each sample calculate the sample average,  $\bar{X}$ , and the sample **range**. For each sample record any unusual settings (e.g., new operator, problem with raw material) that may cause an out-of-control condition.
4. After about 20 to 30 subgroups have been collected, calculate

$$\bar{\bar{X}} = \frac{\sum \bar{X}}{g}; \quad \bar{R} = \frac{\sum R}{g}$$

where  $\bar{\bar{X}}$  is the average of averages,  $\bar{R}$  is the average of range, and  $g$  is the number of samples or subgroups.

5. Trial upper and lower control limits for the  $\bar{X}$  and  $R$  chart are calculated as follows:

$$\begin{aligned} \text{UCL}_{\bar{X}} &= \bar{\bar{X}} + A_2 \bar{R}; & \text{UCL}_R &= D_4 \bar{R} \\ \text{LCL}_{\bar{X}} &= \bar{\bar{X}} - A_2 \bar{R}; & \text{LCL}_R &= D_3 \bar{R} \end{aligned}$$

$A_2$ ,  $D_3$ , and  $D_4$  are constants and are functions of sample sizes used. These constants are used to approximate process standard deviation from the range. Tables of these constants are provided in Banks [1989], De Vor *et al.* [1992], Grant and Leavenworth [1988], and Montgomery [1991].

6. Plot the sample averages and ranges on the  $\bar{X}$  and the  $R$  chart, respectively. Any out-of-control point that has an assignable cause (new operator, etc.) is discarded.
7. Calculate the revised control limits as follows:

$$\bar{X}_o = \frac{\sum \bar{X} - \sum \bar{X}_d}{g - g_d}; \quad R_o = \frac{\sum R - \sum R_d}{g - g_d}; \quad \sigma_o = \frac{R_o}{D_2}$$

$$\begin{aligned} \text{UCL}_{\bar{X}_o} &= \bar{X}_o + A\sigma_o & \text{UCL}_R &= D_2\sigma_o \\ \text{LCL}_{\bar{X}_o} &= \bar{X}_o - A\sigma_o & \text{LCL}_R &= D_1\sigma_o \end{aligned}$$

The subscript  $o$  and  $d$  stand for revised and discarded terms, respectively. The revised control charts will be used for the next production period by taking samples of the same size and plotting the sample average and sample range on the appropriate chart. The control limits will remain in effect until one or more factors in the process change. Figure 161.4 shows control charts of  $\bar{X}$  and  $R$  values for ten subgroups. Each subgroup contained five observations because none of the ten data points lie outside of either upper and lower control limits; the process is designated "in control."

**Figure 161.4** Control charts for  $\bar{X}$  and  $R$ .

The control charts can be used to monitor the out-of-control conditions of the process. It is imperative to realize that patterns of variation as plotted on the charts should give clear indications to a process that is headed for an out-of-control condition or one that displays an abnormal pattern of variations. Whereas no point may actually fall out of the limits, variation patterns can often point to some unusual process behavior that requires careful study of the process.

## Control Charts for Attributes

For those quality characteristics that are not easily measured—or in such cases where count of defects or defective items are involved or go-no-go gages are used—control charts for attributes are used. These charts can be grouped into two major categories:

1. Charts for defectives or nonconforming items
2. Charts for defects or nonconformities

### Charts for Nonconforming Items

The basic charts in this group are the fraction **nonconforming** chart ( $p$  chart), percent nonconforming chart ( $100p$  chart), and count of nonconforming chart ( $np$  chart). The procedure for the construction, revision, and the interpretation of control charts for attributes is similar to that for

$\bar{X}$  and  $R$  charts. The following steps may be used to construct a  $p$  chart:

1. Once sample size has been established, fraction nonconforming,  $p$ , is determined for each sample by

$$p = \frac{np}{n}$$

where  $n$  is the sample size and  $np$  is the count of defectives or nonconforming items in the sample.

2. After roughly 20–30 subgroups have been collected, calculate  $\bar{p}$ , the value of the central line, or the average fraction defective.

$$\bar{p} = \frac{\sum np}{\sum n}$$

3. Trial control limits are calculated using:

$$UCL = \bar{p} + 3\sqrt{\frac{\bar{p}(1 - \bar{p})}{n}}$$

$$LCL = \bar{p} - 3\sqrt{\frac{\bar{p}(1 - \bar{p})}{n}}$$

4. Plot the fraction defective for each subgroup. The out-of-control subgroups that have assignable causes are discarded, and revised limits are calculated as follows:

$$p_o = \frac{\sum np - \sum np_d}{\sum n - n_d}$$

$$UCL = p_o + 3\sqrt{\frac{p_o(1 - p_o)}{n}}$$

$$LCL = p_o - 3\sqrt{\frac{p_o(1 - p_o)}{n}}$$

5. If the lower control limit is a negative number, it is set to zero. Sample points that fall above the upper limit indicate a process that is out of control. However, samples that fall below the lower limit, when the lower control limit is greater than zero, indicate a product that is better than expected. In other words, if a sample contains fewer nonconforming items than the process is capable of producing, the sample fraction defective will fall below the lower control limit. For this reason some practitioners may choose to set the lower limit of the attribute charts to zero. This practice, however, may mask other problems or potentials for process improvements.

Other charts for nonconforming items are simple variations of the  $p$  chart. In the case of the  $100p$  chart, all values of the  $p$  chart are expressed as percentages. In the case of the  $np$  chart, instead of plotting fraction or percent defectives, actual counts of nonconforming or defective items are plotted. See Banks [1989], De Vor *et al.* [1992], Grant and Leavenworth [1988], and Montgomery [1991] for greater detail. The formulas for the central line and the control limits for an  $np$  chart are given below. It is assumed that the revised value for universe fraction defective,  $p$ , is known. If  $p$  is not known, then the procedure for the  $p$  chart must be carried out to determine the revised value for the universe fraction defective.

$$\begin{aligned}\text{Central line} &= np_o \\ \text{Control limits} &= np_o \pm 3\sqrt{np_o(1 - p_o)}\end{aligned}$$

where  $n$  is the sample size and  $p_o$  is the universe fraction defective.

### Charts for Defects or Nonconformities

Whereas the charts for defective or nonconforming items are concerned with the overall quality of an item or sample, charts for defects look at each defect (i.e., blemish, scratch, etc.) in each item or sample. One may consider an item a nonconforming item based on its overall condition. A defect or **nonconformity** is that condition that makes an item a nonconforming or defective item.

In this category are  $c$  charts and  $u$  charts. The basic difference between the two is the sample size. The sample size,  $n$ , for a  $c$  chart is equal to one. In this case the number of nonconformities or defects are counted per a single item. For a  $u$  chart, however,  $n > 1$ . See Banks [1989], De Vor *et al.* [1992], Grant and Leavenworth [1988], and Montgomery [1991] for the formulas and construction procedures.

## 161.3 Tolerances and Capability

---

As stated earlier, *process capability* refers to the range of process variation that is due to chance or natural process deviations. This was defined as  $\bar{X} \pm 3\sigma$  (also referred to as  $6\sigma$ ) which is the expected or natural process variation. **Specifications** or **tolerances** are dictated by design engineering and are the maximum amount of acceptable variation. These specifications are often stated without regard to process spread. The relationships between the process spread or the natural process variation and the engineering specifications or requirements are the subject of process capability studies. Process capability can be expressed as:

$$C_p = \frac{US - LS}{6\sigma}$$

where

$C_p$  = process capability index

US = upper engineering specification value

LS = lower engineering specification value

A companion index,  $C_{pk}$ , is also used to describe process capability, where

$$C_{pk} = \frac{US - \bar{X}}{3\sigma}$$

or

$$C_{pk} = \frac{\bar{X} - LS}{3\sigma}$$

The lesser of the two values indicates the process capability. The  $C_{pk}$  ratio is used to indicate whether a process is capable of meeting engineering tolerances and whether the process is centered around the target value  $\bar{X}$ . If the process is centered between the upper and the lower specifications,  $C_p$  and  $C_{pk}$  are equal. However, if the process is not centered,  $C_{pk}$  will be lower than  $C_p$  and is the true process capability index. See De Vor *et al.* [1992], Grant and Leavenworth [1988], and Montgomery [1991] for additional information.

A capability index less than one indicates that the specification limits are much tighter than the process spread. Hence, although the process may be in control, the parts may well be out of specification. Thus the process does not meet engineering requirements. A capability index of one means that as long as the process is in control, parts are also in-spec. The most desirable situation is to have a process capability index greater than one. In such cases, not only are approximately 99.73% of the parts in-spec when the process is in control, but even if the process should go out of control, the product may still be within the engineering specifications. Process improvement efforts are often concerned with reducing the process spread and, therefore, increasing the process capability indices.

An extremely powerful tool for isolating and determining those factors that significantly contribute to process variation is statistical design and analysis of experiments. Referred to as "design of experiments," the methodology enables the researcher to examine the factors and determine how to control these factors in order to reduce process variation and therefore increase process capability index. For greater detail, see Box *et al.* [1978].

## Defining Terms

**Assignable causes:** Any element that can cause a significant variation in a process.

**Frequency distribution:** Usually a graphical or tabular representation of data. When scores or measurements are arranged, usually in an ascending order, and the occurrence (frequency) of each score or measurement is also indicated, a frequency distribution results.

No. of Defectives	Frequency
0	10
1	8
2	7
3	8
4	6
5	4
6	2
7	1
8	1
9	0

The frequency distribution indicates that ten samples were found containing zero defectives.

**Nonconforming:** A condition in which a part does not meet all specifications or customer requirements. This term can be used interchangeably with *defective*.

**Nonconformity:** Any deviation from standards, specifications, or expectation; also called a *defect*. Defects or nonconformities are classified into three major categories: critical, major, and minor. A critical nonconformity renders a product inoperable or dangerous to operate. A major nonconformity may affect the operation of the unit, whereas a minor defect does not affect the operation of the product.

**Population:** An entire group of people, objects, or phenomena having at least one common characteristic. For example, all registered voters constitute a population.

**Quality:** Quality within the framework of manufacturing is defined as conformance to requirements.

**Range:** A measure of variability or spread in a data set. The range of a data set,  $R$ , is the difference between the highest and the lowest values in the set.

**Sample:** A small segment or subgroup taken from a complete population. Because of the large size of most populations, it is impossible or impractical to measure, examine, or test every member of a given population.

**Specifications:** Expected part dimensions as stated on engineering drawings.

**Standard deviation:** A measure of dispersion or variation in the data. Given a set of numbers, all of equal value, the standard deviation of the data set would be equal to zero.

**Tolerances:** Allowable variations in part dimension as stated on engineering drawings.

## 162.1 Flexible Machining

An Example of FMS

## 162.2 Flexible Assembly

## 162.3 The Economic Justification of Flexibility

**Andrew Kusiak**

*University of Iowa*

**Chang-Xue Feng**

*University of Iowa*

Flexible manufacturing systems (FMSs) have emerged to meet frequently changing market demands for products. The distinguishing feature of an FMS is in its software (e.g., numerical control programs) rather than the hardware (using, for example, relays and position switches). Fixed automation, programmable automation, and flexible automation are the three different forms of automation [Groover *et al.*, 1986]. Numerical control (NC) and computer numerical control (CNC) technologies are essential in FMSs. Developments in robotics, automated guided vehicles (AGVs), programmable controllers (PCs), computer vision, group technology (GT), and statistical quality control (SQC) have accelerated the applications of FMSs. The computer technology (hardware and software) is a critical factor in determining the performance of flexible manufacturing systems. An FMS is frequently defined as a set of CNC machine tools and other equipment that are connected by an automated material-handling system, all controlled by a computer system [Askin and Standridge, 1993].

The FMS concept has been applied to the following manufacturing areas [Kusiak, 1986]: (1) fabrication, (2) machining, and (3) assembly. An FMS can be divided into three subsystems [Kusiak, 1985]: (1) management system, (2) production system, and (3) material-handling system. The management system incorporates computer control at various levels; the production system includes CNC machine tools and other equipment (e.g., inspection stations, washing stations); the material handling system includes AGVs, robots, and automated storage/retrieval systems (AS/RSs).

The planning, design, modeling, and control of an FMS differs from the classical manufacturing system. The structure and taxonomy of an FMS has been studied in Kusiak [1985]. Some planning tools—for example, IDEF (the U.S. Air Force ICAM definition language) [U.S. Air Force, 1981]—have been proposed for modeling of material flow, information flow, and dynamic

(simulation) modeling of an FMS. Numerous mathematical models of FMSs are discussed in Askin and Standridge [1993]. An FMS can be structured as a five-level hierarchical control model [Jones and McLean, 1986] (see Table 162.1).

**Table 162.1** FMS Control Architecture (National Institute of Standards and Technology) [Jones and McLean, 1996]

Level	Planning Horizon	Functions
1. Facility	Months to years	Information management Manufacturing engineering Production management
2. Shop	Weeks to months	Task management Resource allocation
3. Cell	Hours to weeks	Task analysis Batch management Scheduling Dispatching Monitoring
4. Workstation	Minutes to hours	Setup Equipment sequencing In-process inspection
5. Equipment	Milliseconds to minutes	Machining Measurement Handling Transport Storage

Manufacturing concepts such as just-in-time (JIT) manufacturing, lean manufacturing, and agile manufacturing relate to the flexible manufacturing approach. Here the term *flexible* describes the system's ability to adjust to customers' preferences; JIT reduces the throughput time and the level of inventory; "lean" stresses efficiency and cost reduction; and "agile" addresses the speed of a manufacturing system in responding to the changing market demands. Other terms such as flexible manufacturing cells (FMCs), computer-aided manufacturing (CAM), and computer integrated manufacturing (CIM) are frequently used to describe flexible manufacturing.

## 162.1 Flexible Machining

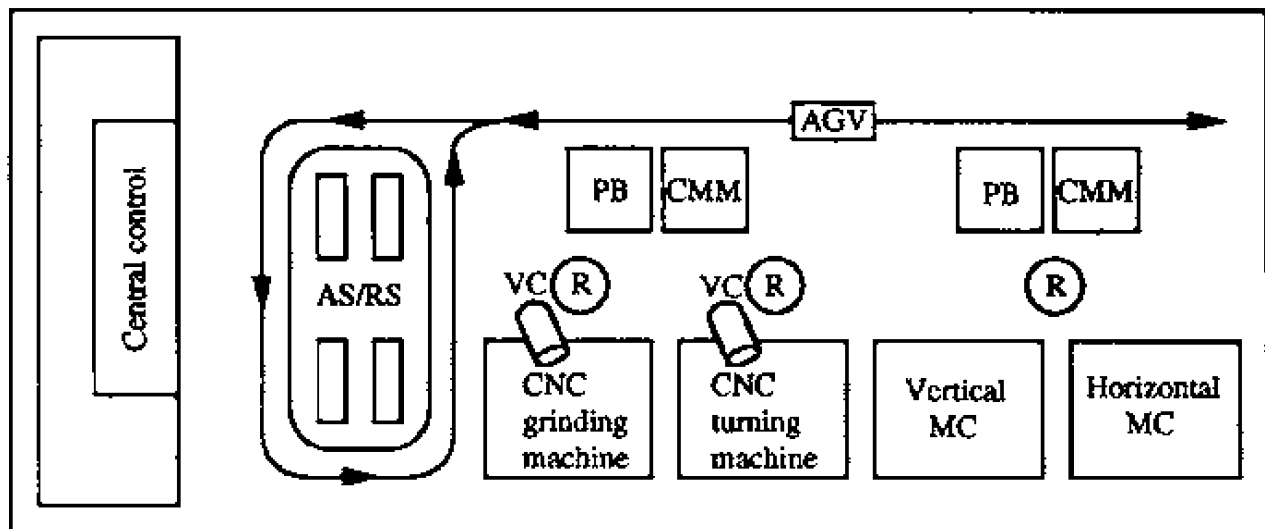

The basic features of a flexible machining system (FMS), as well as the differences between a flexible machining system and the equivalent classical machining system, are presented in Kusiak [1990] in the form of eight observations. These observations are based on the analysis of over 50 flexible machining systems; for each observation, a brief justification is provided.

### An Example of FMS

Figure 162.1 illustrates one type of flexible machining system (FMS). The FMS produces parts for

a family of DC motors used in the FANUC CNC system. The parts are of two types: rotational (e.g., a motor shaft) and prismatic (e.g., a supporting house). The production system includes a CNC turning machine tool, a CNC grinding machine tool, a vertical machining center, and a horizontal machining center, as well as two coordinate-measuring machines (CMMs). Programmable controllers (PCs) are also used in the CNC control system to perform some auxiliary functions. Quite frequently, a PC can be used as an independent CNC control device in a position control mode (as opposed to a path control mode), for example, in a CNC drilling machine to directly drive the servo motor. A CMM measures automatically the precision of the machined parts, including their nominal values and tolerances. It includes a moving head, a probe, a microcomputer, and input/output (I/O) devices. It is controlled by an NC program, and it feeds the measured data to the corresponding CNC system and records them for the purpose of statistical quality control (SQC). The essential function of the SQC system is to analyze the data from the CMM and to construct an X-bar chart, which shows the measured values and their mean value based on a predetermined sample size and grouping. This mean value and the changing range are then compared to the designed nominal value and tolerance, respectively, to determine whether the process is under control.

**Figure 162.1** Physical layout of a flexible machining system. AS/RS: automated storage and retrieval system; PB: part buffer; CMM: coordinate-measuring machine; R: robot; VC: video camera; MC: machining center.

The automated material handling system in Fig. 162.1 includes an AGV, three robots, two part buffers, and the automated storage and retrieval system (AS/RS). The function of the AGV in Fig. 162.1 is to transfer loads to remote locations following a guided path. For the long-distance handling in this FMS, a robot cannot provide the mobility of an AGV, and a conveyor does not offer the flexibility desired. The AGV sends the raw material from the AS/RS to the part buffer of each workstation and brings back the finished products from the part buffers to the AS/RS. An industrial robot is a reprogrammable, multifunctional manipulator designed to move materials,

parts, tools, or special devices through variable programmed motions for the performance of a variety of tasks (Robotics Industries Association). In the system in Fig. 162.1 the three robots load parts from part buffers to each CNC machine tool, transfer parts from the CNC machine tools to the CMMs, and unload parts from machines to the part buffers. The AS/RS is used to temporarily store the raw material and finished product. Although the AGV and the robots in the system in Fig. 162.1 function separately, it is possible for them to work jointly to provide both mobility and flexibility. For example, an AGV can be interfaced with a robot to provide more flexible loading and unloading capability, and a robot can be mounted on an AGV to achieve mobility.

The control and management system includes the central control minicomputer, the microcomputer resided in each CNC machine and robot, and two industrial video cameras. The computer control system performs two fundamental functions: monitoring and control. For example, it stores process plans and NC programs; dispatches programs to the individual pieces of equipment; controls the production, traffic, tools, and quality; monitors the material handling system; and monitors and reports the system performance. The video camera (VC) monitors the critical machining processes. A VC might or might not have the capability to analyze and process the data collected. In the former case it can process the image based on computer vision technology and inform the CNC system; in the latter case a human expert monitors the image taken by the VC and then manually informs the corresponding CNC system. Other types of monitoring might be used in an FMS, for example, measuring the cutting force, torque, or power. In some types of monitoring a measuring head may be placed in the tool magazine and used to measure the machining quality of certain operations as required. The use of the manufacturing automation protocol (MAP) in manufacturing is reaching a momentum. The equipment purchased from different vendors is linked through a shop local-area network (LAN), as the vendors tend to adopt the MAP standard. Tool management is one of the functions of the computer control system [Kusiak 1990].

## 162.2 Flexible Assembly

---

Most of the observations regarding the flexible machining systems [Kusiak, 1990] apply to the flexible assembly systems (FASs) as well. Any differences that may arise are of terminology rather than concept. The earliest FASs were designed for assembling printed circuit boards. More recent FASs have been developed for mechanical assembly. The automated material-handling system—including AGVs, conveyors, and robots—is more important in an FAS than an FMS. The design of a product is more closely related to the design and operations of an FAS than to that of a component with a flexible machining system. Boothroyd *et al.* [1982] discusses in depth rules for design of products for automated assembly, including flexible assembly systems. Another widely used design for assembly method, the assembly evaluation method (AEM), was developed at Hitachi. The basic design for assembly (DFA) rules include:

1. Minimize the number of components in a product.
2. Ensure that a product has a suitable base (part) on which the assembly can be built.

3. Ensure that the product base has features that will enable it to be readily located in a suitable position in the horizontal plane.
4. Minimize the number of assembly directions; if possible, use only top-down, vertical assembly motions.
5. If possible, design the product so that it can be assembled in layers.
6. Provide chamfers or tapers to help the component be easily positioned.
7. Avoid expensive and time-consuming fastening operations and avoid using assembly tools (e.g., screwdrivers).
8. Design the product so that the assembly does not have to be lifted or rotated, since the lifting and rotating results in complicated fixtures and grippers, more degrees of freedom of the robot, and increased cycle time.
9. Design the product to simplify packaging. The more uniform and simple the product packaging is, the easier it will be to apply a robotic packaging station that uses standard carts and pallets.
10. Use symmetric features whenever possible; otherwise, exaggerate asymmetry to facilitate identification and orientation of components.
11. Design a component to avoid tangling when feeding.
12. Design product variations to allow common handling and assembly methods.

An example of mechanical product design for flexible assembly is presented in Elmaraghy and Knoll [1989]. The authors discuss design for flexible assembly of a family of DC motors and the design of the flexible assembly system.

The IBM Proprinter is a frequently cited example of an electronic product that was designed for flexible automated assembly. The goals for the printer design were relatively simple:

- Develop a modular design.

- Minimize the total number of parts.

- All parts are to be self-aligning for ease of assembly.

Other principles of design for assembly that were used in this example are as follows:

- No fasteners

- No springs

- No pulleys

- No excess modules

- No adjustment

- No labels

- No paint

- No extra parts

- No multidirectional assembly

- No alignment/location tools or fixtures

- No external tests

- No engineering change notices (ECNs)

No custom builds or options  
No manual assembly

## 162.3 The Economic Justification of Flexibility

---

Flexibility is a critical objective in design, planning, and operating an FMS. An FMS is intended to accommodate a large number of types of products and allow for more changes of products and higher equipment utilization, whereas in lean and agile manufacturing, flexibility means not only more changes and more product types, but also quicker changes, plus a reasonable rather than ultimately high utilization. Although none of the definitions of manufacturing flexibility have been generally accepted, the following types of flexibility are frequently considered: machine flexibility, process flexibility, product flexibility, routing flexibility, volume flexibility, expansion flexibility, process sequence flexibility, operation flexibility, and production flexibility. How to price the product produced in an FMS causes difficulties and often creates conflicts between accounting and engineering departments. There is some evidence that the U.S. and Japan operate FMSs in radically different ways. Jaikumar [1986] shows that Japanese users had achieved at the time greater flexibility and yet shorter development time than users in the U.S.

Edward M. Knod, Jr.. “Management and Scheduling”  
*The Engineering Handbook*.  
Ed. Richard C. Dorf  
Boca Raton: CRC Press LLC, 2000

## Management and Scheduling

---

### 163.1 Management: Definition and Innovations

Duties and Activities • Requisite Skills and Attributes • Trends and Innovations • Principles for Managing Operations

### 163.2 Scheduling

Relationship to Planning • Effects of Manufacturing Environment • Effects of Contemporary Management Practices

### **Edward M. Knod, Jr.**

*Western Illinois University*

Prescriptions for how managers ought to establish and maintain world-class excellence in their organizations changed substantially during the 1980s and 1990s. Emerging markets, shifting patterns of global competitiveness and regional dominance in key industries, the spread of what might be called Japanese management and manufacturing technologies, and the philosophy and tools of the total quality movement are among the factors that combined to usher in a heightened focus on the overall capacity required to provide continuous improvement in meeting evolving customer needs. The effects of this contemporary management approach first appeared in manufacturing [[Schonberger, 1982](#); [Hall, 1983](#)] and continue to have profound influence in that sector. Changes in the way managers approach scheduling serve to exemplify the new thinking.

This chapter begins with an overview of contemporary management, continues with a discussion of scheduling in various manufacturing environments, and concludes with references and suggested sources of additional information.

### **163.1 Management: Definition and Innovations**

---

In a somewhat general-to-specific progression, management in contemporary competitive manufacturing organizations may be described by (1) duties and activities, (2) requisite skills and attributes, (3) trends and innovations, and (4) principles for managing operations.

### **Duties and Activities**

Briefly, the goal of management is to ensure organizational success in the creation and delivery of goods and services. Popular definitions of management often employ lists of activities that describe

what managers do. Each activity serves one or more of three general, and overlapping, duties: creating, implementing, and improving.

- *Creating.* Activities such as planning, designing, staffing, budgeting, and organizing accomplish the creativity required to build and maintain customer-serving capacity. Product and process design, facility planning and layout, work-force acquisition and training, and materials and component sourcing are among the tasks that have a substantial creative component.
- *Implementing.* When managers authorize, allocate, assign, schedule, or direct, emphasis shifts from creating to implementing—putting a plan into action. (A frequent observation is that the biggest obstacle to successful implementation is lack of commitment.) During implementation, managers also perform controlling activities—that is, they monitor performance and make necessary adjustments.
- *Improving.* Environmental changes, (e.g., new or revised customer demands, challenges from competitors, and social and regulatory pressures) necessitate improvements in output goods and services. In response to—or better yet, in anticipation of—those changes, managers re-create—that is, they start the cycle again with revised plans, better designs, new budgets, and so forth.

Outcomes, desirable or otherwise, stem from these activities. A goal-oriented manager might describe the aim of the job as "increased market share" or "greater profitability," but he or she will try to attain that goal by creating, implementing, and improving.

## Requisite Skills and Attributes

Exact requirements are hard to pin down, but any skill or attribute that helps a manager make better decisions is desirable. Bateman and Zeithaml [1993] suggest that managers need technical skills, interpersonal and communications skills, and conceptual and decision skills. Extension of these broad categories into job-specific lists is perhaps unwarranted given current emphasis on cross-functional career migration and assignments to interdisciplinary project teams or product groups. Sound business acumen and personal traits such as ethical demeanor, good time-management habits, and pleasant personality, however, are general attributes that serve managers in any job. More recently, emphasis on computer (and information system) literacy and knowledge of foreign languages and customs has increased as well.

## Trends and Innovations

An array of publications, seminars, and other vehicles for disseminating "how and why" advice has bolstered the spread of contemporary management theory and research. Manufacturing managers constitute the primary target audience for much of this work. The information bounty can be reduced, tentatively, to a set of core trends and innovative approaches. [Table 163.1](#) offers a short list of seven concept areas within which numerous interrelated trends or innovations have emerged. They are dominant themes in contemporary management literature and in that regard help define what today's managers are all about.

**Table 163.1** Trends and Innovations in Management

---

**Customers at center stage.** The customer is the next person or process—the destination of one's work. The provider-customer chain extends, process to process, on to final consumers. Whatever a firm produces, customers would like it to be better, faster, and cheaper; prudent managers therefore embrace procedures that provide *total quality, quick responses, and waste-free* (economical) *operations*. These three aims are mutually supportive and form the core rationale for many of the new principles that guide managers.

**Focus on improvement.** Managers have a duty to embrace improvement. A central theme of the total quality (TQ) movement is constant improvement in output goods and services and in the processes that provide them. Sweeping change over the short run, exemplified by business process reengineering [Hammer and Champy, 1993], anchors one end of the improvement continuum; the rationale is to discard unsalvageable processes and start over so as not to waste resources in fruitless repair efforts. The continuum's other end is described as incremental continuous improvement and is employed to fine-tune already-sound processes for evenbetter results.

**Revised "laws" of economics.** Examples of the contemporary logic include the following. Quality costs less, not more. Costs should be allocated to the activities that cause their occurrence. Prevention (of errors) is more cost-effective than discovery and rework. Training is an investment rather than an expense. Value counts more than price (e.g., in purchasing). Desired market price should define (target) manufacturing cost, notthe reverse.

**Elimination of wastes.** Waste is anything that doesn't add value; it adds cost, however, and should be eliminated. Waste detection begins with two questions: "Are we doing the right things?" and "Are we doing those things in the right way?" Toyota identifies seven general categories of wastes [Suzaki, 1987, ch. 1], each with several subcategories. Schonberger [1990, ch. 7] adds opportunities for further waste reduction by broadening the targets to include nonobvious wastes. Simplification or elimination of indirect and support activities (e.g., production planning, scheduling, and control activities; inventory control; costing and reporting, etc.) is a prime arena for contemporary waste-reduction programs [Steudel and Desruelle, 1992, ch. 8].

**Quick-response techniques.** Just-in-time (JIT) management, queue-limiters, reduced setups, better maintenance, operator-led problem solving, and other procedures increase the velocity of material flows, reduce throughput times, and eliminate the need for many interdepartmental control transactions. Less tracking and reporting (which add no value) reduces overhead. Collectively, quick-response programs directly support faster customer service [Blackburn, 1991, ch. 11].

**The process approach.** The **process** approach has several advantages [Schonberger and Knod, 1994, ch. 4]. Processes cut across functional departments; attention is drawn to overall or group results, ideally by a cross-functional team that may also include customers and suppliers. Processes are studied at the job or task level, or at the more detailed operations level. Automation can be beneficial after' process waste is removed and further reduction in variation is needed. Tools for measurement and data analysis, methods improvement, and team building are among those needed for successful process improvement.

**Human resources management.** Increased reliance on self-directed teams (e.g., in cells or product groups) and/or on-line operators for assumption of a larger share of traditional management responsibilities is a product of the management revolution of the 1980s that had noticeable impact in the 1990s. Generally, line or shop employees have favored those changes; they get more control over their workplaces. There is a flipside: As employee empowerment shifts decision-making authority, as JIT reduces the need for many reporting and control activities, and as certain supervisory and support-staff jobs are judged to be non-value-adding, many organizations downsize. Lower and mid-level managers and support staff often bear the job-loss burden.

---

# Principles for Managing Operations

The final and most detailed component of this general-to-specific look at contemporary management is a set of action-oriented, prescriptive principles for managing operations in any organization; see [Table 163.2](#). The principles apply to managers at any level and define ways for increasing competitiveness in manufacturing organizations. Brief supporting rationale and techniques or procedures that exemplify each principle appear in the right-hand column; Schonberger and Knod [[1994](#), ch. 1] provide a more detailed discussion.

**Table 163.2** Principles for Managing Operations

	Principle	Rationale and Examples
1.	Get to know customers; team up to form partnerships and share process knowledge.	Providers are responsible for getting to know their customers' processes and operations. By so doing, they offer better and faster service, perhaps as a member of customers' teams.
2.	Become dedicated to rapid and continual increases in quality, flexibility, and service; and decreases in costs, response or lead time, and variation from target.	The logic of continuous improvement, or <i>kaizen</i> [ <a href="#">Imai, 1986</a> ], rejects the "if it ain't broke" philosophy; seeks discovery and then prevention of current and potential problems; and anticipates new or next-level standards of excellence.
3.	Achieve unified purpose through shared information and cross-functional teams for planning/design, implementation, and improvement efforts.	Information sharing keeps all parties informed. Early manufacturing/supplier involvement (EMI/ESI), and concurrent or simultaneous product and process design are components of the general cross-functional team design concept.
4.	Get to know the competition and world-class leaders.	Benchmarking [ <a href="#">Camp, 1989</a> ] elevates the older notion of "reverse engineering" to a more formal yet efficient means of keeping up with technology and anticipating what competitors might do. Search for best practices.
5.	Cut the number of products (e.g., types or models), components, or operations; reduce supplier base to a few good ones and form strong relationships with them.	Product line trimming removes nonperformers; component reduction cuts lead times by promoting simplification and streamlining. Supplier certifications and registrations (e.g., ISO 9000) lend confidence, allow closer partnering with few suppliers (e.g., via EDI), and reduce overall buying costs.
6.	Organize resources into multiple chains of customers, each focused on a family of products or services; create cells, flow lines, plants-in-a-plant.	Traditional functional organization by departments increases throughput times, inhibits information flow, and can lead to "turf battles." Flow lines and cells promote focus, aid scheduling, and employ cross-functional expertise.
7.	Continually invest in human resources through cross-training for mastery of multiple skills, education, job and career path rotation, health and safety, and security.	Employee involvement programs, team-based activities, and decentralized decision responsibility depend on top-quality human resources. Cross-training and education are keys to competitiveness. Scheduling—indeed, all capacity management—is easier when the work force is flexible.
8.	Maintain and improve present equipment and human work before acquiring new equipment, then automate incrementally	<i>TPM</i> , total productive maintenance, [ <a href="#">Nakajima, 1988</a> ] helps keep resources in a ready state and facilitates scheduling by decreasing unplanned downtime, thus increasing capacity.

	when process variability cannot otherwise be reduced.	Also, process improvements must precede automation; get rid of wasteful steps or dubious processes first.
9.	Look for simple, flexible, movable, and low-cost equipment that can be acquired in multiple copies—each assignable to a focused cell, flow line, or plant-in-a-plant.	Larger, faster, general-purpose equipment can detract from responsive customer service, especially over the longer run. A single fast process is not necessarily divisible across multiple customer needs. Simple, dedicated equipment is an economical solution; setup elimination is an added benefit.
10.	Make it easier to make/provide goods and services without error or process variation.	The aim is to prevent problems or defects from occurring—the fail-safing ( <i>pokayoke</i> ) idea—rather than rely on elaborate control systems for error detection and the ensuing rework. Strive to do it right the first time, every time.
11.	Cut cycle times, flow time, distance, and inventory all along the chain of customers.	Time compression provides competitive advantage [Blackburn, 1991]. Removal of excess distance and inventory aids quick response to customers. Less inventory also permits quicker detection and correction of process problems.
12.	Cut setup, changeover, get-ready, and startup times.	Setup (or changeover) time had been the standard excuse for large-lot operations prior to directed attention at reduction of these time-consuming activities [Shingo, 1985]. Mixed-model processing demands quick changeovers.
13.	Operate at the customer's rate of use (or a smoothed representation of it); decrease cycle interval and lot size.	Pull-mode operations put the customer in charge and help identify bottlenecks. Aim to synchronize production to meet period-by-period demand rather than rely on large lots and long cycle intervals.
14.	Record and <i>own</i> quality, process, and problem data at the workplace.	When employees are empowered to make decisions and solve problems, they need appropriate tools and process data. Transfer of point-of-problem data away from operators and to back-office staff inhibits responsive, operator-centered cures.
15.	Ensure that front-line associates get first chance at problem solving—before staff experts.	Ongoing process problems and on-the-spot emergencies are most effectively solved by teams of front-line associates; staff personnel are best used in advisory roles and for especially tough problems.
16.	Cut transactions and reporting; control <i>causes</i> , not symptoms.	Transactions and reports often address problem symptoms (e.g., time or cost variances) and delay action. Quick-response teams, using data-driven logic, directly attack problem causes and eliminate the need for expensive reporting.

## 163.2 Scheduling

---

Basically, **scheduling** refers to the activities through which managers allocate capacity for the near future. It includes the assignment of work to resources, or vice versa, and the determination of

timing for specific work elements and thus answers the questions "who will do what" and "when will they do it." In manufacturing the scheduling time horizon is usually weekly, daily, or even hourly. In general, scheduling (1) flows from and is related to planning, (2) is determined by manufacturing environment, and (3) can be simplified when appropriate management principles are followed.

## Relationship to Planning

The planning activity also answers the "who," "what," and "when" questions, but in more general or aggregate terms for the longer time horizon—typically months, quarters, or years into the future. So, in the temporal sense, scheduling is short-term planning. But planning involves more. With the other creative activities, planning also addresses the characteristics of what is to be done (e.g., designs), quantity and variety (e.g., the product mix), how work will be accomplished (e.g., methods and procedures), utilization of funds (e.g., budgeting), and so on—including how scheduling itself will be accomplished. When planning (or design) has been thorough and things go according to plan, little creativity should be required in scheduling; it ought to be mostly an implementation activity.

In manufacturing, aggregate demand forecasts are filtered by business plans and strategies—what the company wants to do—to arrive at aggregate capacity and production plans. The master schedule states what the company plans to provide, in what quantities, and when. To the extent that on-hand or previously-scheduled inventories are insufficient to meet the commitments described by the master schedule, additional purchasing and production are required. Consequently, detailed planning and scheduling activities—for fabrication of components and subassemblies and for final assembly operations—come into play. Scheduling is among the production activity control duties that form the "back end" of the total manufacturing planning and control (MPC) system [Vollmann *et al.*, 1992]. Thus, it might be said that scheduling flows from planning.

## Effects of Manufacturing Environment

The type of manufacturing environment determines the nature of scheduling, as shown in Table 163.3. As the table notes, project and repetitive/continuous environments present less extreme scheduling problems; the sources listed at the end of this chapter contain suitable discussion. For project scheduling, see Evans [1993, ch. 18], Kerzner [1989, ch. 12], and Schonberger and Knod [1994, ch. 14]. For scheduling in repetitive or continuous production, see Schniederjans [1993, ch. 3 and 6] and Schonberger and Knod [1994, ch. 11 and 12].

**Table 163.3** Manufacturing Scheduling Overview

Manufacturing Environment	General Nature of Scheduling
Project	Activity scheduling and controlling (as well as overall project planning) may rely on Program Evaluation and Review Technique (PERT) or Critical Path Method (CPM). Large project complexity, cost, and uncertainties involved justify these tools. Smaller

Job or Batch	projects and single tasks may be scheduled with Gantt charts. Scheduling is time consuming due to low- or intermediate-volume output coupled with irregular production of any given item. Production typically occurs on flexible resources in functional or process layouts where considerable variation in products, routings, lot sizes, and cycle times-along with the competition among jobs (customers) for resource allocation-adds to the scheduling burden. Rescheduling may be common.
Continuous or Repetitive	Regular—if not constant—production on equipment dedicated to one or a few products (e.g., lines or cells) combine to decrease the scheduling problem. In process flow systems, scheduling is minimal except for planned maintenance, equipment or product changeovers, and so forth. In repetitive production, line balancing may be used to assign work; JIT's pull system, regularized schedules, and mixed-model scheduling can closely synchronize output with demand and can accommodate demand variation.

---

The variabilities inherent with traditional batch and job environments create the most complex scheduling (and control) problems. *Loading* (allocation of jobs to work centers), *sequencing* (determining job-processing order), *dispatching* (releasing jobs into work centers), *expediting* (rushing "hot" jobs along), and *reporting* (tracking job progress along routes) are among the specific activities. *Assignment models* can be of assistance in loading, and *priority rules* may be used for sequencing and dispatching. In batch operations, *lot splitting* and *overlapping* may help expedite urgent jobs. Unfortunately, however, throughput time in many job operations consists largely of queue time, setup time, move time, and other non-value-adding events. Perhaps even more unfortunate have been managers' attempts to "solve" the complexities of job scheduling and control by relying on more exotic scheduling and control tools.

## Effects of Contemporary Management Practices

This last section closes the discussion of scheduling by appropriately returning to the topic of management. In the 1970s North American managers allowed batch and job production scheduling and control systems to become too complicated, cumbersome, and costly. A more competitive approach lies in the simplification of the production environments themselves [Schonberger and Knod, 1994, ch. 13; Steudel and Desruelle, 1992, ch. 8; Schneiderjans, 1993, ch. 6]. Though necessary to some degree, scheduling itself adds no value to outputs; as such, it ought to be a target for elimination where possible and for streamlining when it must remain. Application of contemporary management practices, such as the principles detailed in Table 163.2, has been shown to improve scheduling, largely by removing the *causes* of the problems—that is, the factors that created a need for complicated and costly scheduling systems.

Steudel and Desruelle [1992] summarize such improvements for scheduling and related production control activities, especially in group-technology environments. Regarding scheduling, they note that manufacturing cells largely eliminate the scheduling problem. Also, sequencing is resolved at the (decentralized) cell level, and mixed-model assembly and kanban more easily handle demand variations. In similar fashion, manufacturing process simplifications foster improvements throughout the production planning and control sequence.

Just-in-time (JIT) management, for example, has been shown to greatly reduce the burden of

these activities, especially scheduling and control [Vollmann *et al.*, 1992, ch. 3 and 5]. Attempts to describe a "JIT scheduling system," however, are unnecessary; it is more productive to devote the effort to eliminating the need for scheduling at all. At this writing, it remains an oversimplification to suggest that the mere pull of customer demand is sufficient to *fully* schedule the factory, but that is a worthy aim. In sum, the less attention managers are required to devote to scheduling, the better.

## Defining Terms

**Management:** Activities that have the goal of ensuring an organization's competitiveness by creating, implementing, and improving capacity required to provide goods and services that customers want.

**Process:** A particular combination of resource elements and conditions that collectively cause a given outcome or set of results.

**Scheduling:** Activities through which managers allocate capacity for the immediate and near-term future.

## Design, Modeling, and Prototyping

---

164.1 The System Design Process

164.2 Rapid Prototyping

164.3 When to Use Modeling and Prototyping

**William L. Chapman**

*Hughes Aircraft Company*

**A. Terry Bahill**

*University of Arizona*

To create a product and the processes that will be used to manufacture it, an engineer must follow a defined system design process. This process is an iterative one that requires refining the requirements, products, and processes of each successive design generation. These intermediate designs, before the final product is delivered, are called **models** or **prototypes**.

A model is an abstract representation of what the final system will be. As such, it can take on the form of a mathematical equation, such as  $f = m \times a$ . This is a deterministic model used to predict the expected force for a given mass and acceleration. This model only works for some systems and fails both at the atomic level, where quantum mechanics is used, and at the speed of light, where the theory of relativity is used. Models are developed and used within fixed boundaries.

Prototypes are physical implementations of the system design. They are not the final design, but are portions of the system built to validate a subset of the requirements. For example, the first version of a new car is created in a shop by technicians. This prototype can then be used to test for aerodynamic performance, fit, drivetrain performance, and so forth. Another example is airborne radar design. The prototype of the antenna, platform, and waveguide conforms closely to the final system; however, the prototype of the electronics needed to process the signal often comprises huge computers carried in the back of the test aircraft. Their packaging in no way reflects the final fit or form of the unit.

### 164.1 The System Design Process

---

The system design process consists of the following steps.

1. Specify the requirements provided by the customer and the producer.
2. Create alternative system design concepts that might satisfy these requirements.

3. Build, validate, and simulate a model of each system design concept.
4. Select the best concept by doing a trade-off analysis.
5. Update the customer requirements based on experience with the models.
6. Build and test a prototype of the system.
7. Update the customer requirements based on experience with the prototype.
8. Build and test a preproduction version of the system and validate the manufacturing processes.
9. Update the customer requirements based on experience with the preproduction analysis.
10. Build and test a production version of the system.
11. Deliver and support the product.

This can be depicted graphically on a spiral diagram as shown in [Fig. 164.1](#).

**Figure 164.1** The system design process.

The process always begins with defining and documenting the customer's needs. A useful tool

for doing this is quality function deployment (QFD). QFD has been used by many Japanese and American corporations to document the voice of the customer. It consists of a chart called the "house of quality." On the left is listed what the customer wants. Across the top is how the product will be developed. These are often referred to as *quality characteristics*. The "whats" on the left are then related to the "hows" across the top, providing a means of determining which quality characteristics are the most important to the customer [Akao, 1990; Bahill and Chapman, 1993].

After the customer's needs are determined the design goes through successive generations as the design cycle is repeated. The requirements are set and a model or prototype is created. Each validation of a model or test of a prototype provides key information for refining the requirements.

For example, when designing and producing a new airborne missile, the initial task is to develop a model of the expected performance. Using this model, the systems engineers make initial estimates for the partition and allocation of system requirements. The next step is to build a demonstration unit of the most critical functions. This unit does not conform to the form and fit requirements but is used to show that the system requirements are valid and that an actual missile can be produced. Requirements are again updated and modified, and the final partitioning is completed. The next version is called the *proof-of-design* missile. This is a fully functioning prototype. Its purpose is to demonstrate that the design is within specifications and meets all form, fit, and function requirements of the final product. This prototype is custom-made and costs much more than the final production unit will cost. This unit is often built partly in the production factory and partly in the laboratory. Manufacturing capability is an issue and needs to be addressed before the design is complete. More changes are made and the manufacturing processes for full production readied. The next version is the proof of manufacturing or the preproduction unit. This device will be a fully functioning missile. The goal is to prove the capability of the factory for full-rate production and to ensure that the manufacturing processes are optimum. If the factory cannot meet the quality or rate production requirements, more design changes are made before the drawings are released for full-rate production. Not only the designers but the entire design and production team must take responsibility for the design of the product and processes so that the customer's requirements are optimized [Chapman *et al.*, 1992]. Also see **Chapters 80, 160, and 161** of this book for additional information on design and production.

Most designs require a model upon which analysis can be done. The analysis should include a measure of all the characteristics the customer wants in the finished product. The concept selection will be based on the measurements done on the models. See **Chapter 188** for more information on selection of alternatives. The models are created by first partitioning each conceptual design into functions. This decomposition often occurs at the same time that major physical components are selected. For example, when designing a new car, we could have mechanical or electronic ignition systems. These are two separate concepts. The top-level function—firing the spark plugs—is the same, but when the physical components are considered the functions break down differently. The firing of the spark plugs is directed by a microprocessor in one design and a camshaft in the other. Both perform the same function, but with different devices. Determining which is superior will be based on the requirements given by the customer, such as cost, performance, and reliability. These characteristics are measured based on the test criteria.

When the model is of exceptional quality a prototype can be skipped. The advances in

computer-aided design (CAD) systems have made wire-wrapped prototype circuit boards obsolete. CAD models are so good at predicting the performance of the final device that no prototype is built. Simulation is repeated use of a model to predict the performance of a design. Any design can be modeled as a complex finite state machine. This is exactly what the CAD model of the circuit does. To truly validate the model each state must be exercised. Selecting a minimum number of test scenarios that will maximize the number of states entered is the key to successful simulation. If the simulation is inexpensive, then multiple runs of this model should be done. See **Chapters 13,29,95,96,97, and 159** for more information on simulations. The more iterations of the design process there are, the closer the final product will be to the customer's optimum requirements.

For other systems, modeling works poorly and prototypes are better. Three-dimensional solids modeling CAD systems are a new development. Their ability to display the model is good, but their ability to manipulate and predict the results of fit, force, thermal stresses, and so forth is still weak. The CAD system has difficulty simulating the fit of multiple parts (such as a fender and car frame) because the complex surfaces are almost impossible to model mathematically. Therefore, fit is still a question that prototypes, rather than models, are best able to answer. A casting is usually used to verify that mechanical system requirements are met.

Computer-aided manufacturing (CAM) systems use the CAD database to create the tools needed for the manufacture of the product. Numerical control (NC) machine instructions can be simulated using these systems. Before a prototype is built, the system can be used to simulate the layout of the parts, the movement of the cutting tool, and the cut of the bar stock on a milling machine. This saves costly material and machine expenses.

Virtual reality models are the ultimate in modeling. Here the human is put into the loop to guide the model's progress. Aircraft simulators are the most common type of this product. Another example was demonstrated when the astronauts had to use the space shuttle to fix the mirrors on the Hubble telescope. The designers created a model to ensure that the new parts would properly fit with the existing design. They then manipulated the model interactively to try various repair techniques. The designers were able to verify fit with this model and catch several design errors early in the process. After this, the entire system was built into a prototype and the repair rehearsed in a water tank [[Hancock, 1993](#)].

Computer systems have also proved to be poor simulators of chemical processes. Most factories rely on design-of-experiments (DOE) techniques, rather than a mathematical model, to optimize chemical processes. DOE provides a means of selecting the best combination of possible parameters to alter when building the prototypes. Various chemical processes are used to create the prototypes that are then tested. The mathematical techniques of DOE are used to select the best parameters based on measurements of the prototypes. Models are used to hypothesize possible parameter settings, but the prototypes are necessary to optimize the process [[Taguchi, 1976](#)].

The progressive push is to replace prototypes with models, because an accurate fully developed model is inexpensively simulated on a computer compared to the cost and time of developing a prototype. A classic example is the development of manned rockets. [Figure 164.2](#) shows the number of test flights before manned use of the rockets.

**Figure 164.2** Flight tests for the manned space program rockets.

The necessity for prototypes diminished rapidly as confidence in computer models developed. Initially, many of the rockets exploded in their first attempts at launch. As more was learned about rocketry, sophisticated models were developed that predicted performance of the rocket based on real-time measurements of valves, temperatures, fuel levels, and so forth. Using modern computers the entire model could be evaluated in seconds and a launch decision made. This eliminated the need for many flight tests and reduced the cost of the entire Apollo moon-landing program.

## 164.2 Rapid Prototyping

Rapid prototyping is the key to reducing design time for parts and processes. Design is an iterative process. By creating prototypes quickly, the design can be completed faster. Japanese automobile manufacturers develop prototypes of their products in 6 months, whereas American companies take 13 months [Womack *et al.*, 1990]. This advantage allows the Japanese companies to get to the market faster, or if they choose they can iterate their design one more time to improve their design's conformance to the customer's requirements. Japanese automakers' ability to create the prototype quickly is due in part to better coordination with their suppliers, but also to the exacting use of design models to ensure that the design is producible.

As seen in Fig. 164.3, the lead in prototype development accounts for 44% of the advantage the Japanese producers have in product development time. The rest of the advantage is from rapid creation of the huge dies needed to stamp out the metal forms of the automobiles. The design of these important manufacturing tools is given as much attention as the final product. By creating flexible designs and ensuring that the teams that will produce the dies are involved in the design process, the die development time is cut from 25 months in the U.S. to 13.8 months in Japan. The rapid creation of the tooling is a key to fast market response.

**Figure 164.3** Comparison of Japanese, American, and European car producers. (Based on Womack, J. P., Jones, D. T., and Roos, D. 1990. *The Machine that Changed the World*. Rawson Associates, New York.

**Stereolithography** is a new method of creating simple prototype castings. The stereolithography system creates a prototype by extracting the geometric coordinates from a CAD system and creating a plastic prototype. The solids model in the CAD system is extracted by "slicing" each layer in the  $z$  axis into a plane. Each layer is imaged by a laser into a bath of liquid photopolymer resin that polymerizes with the energy from the laser. Each plane is added, one on top of the other, to build up the prototype. The final part is cured and polished to give a plastic representation of the solids model. It illustrates the exact shape of the part in the CAD system. This technique will not, however, verify the function of the final product because the plastic material used will not meet strength or thermal requirements [Jacobs, 1992].

Software developers also use rapid prototyping. This technique is used to get a fast though barely functional version of the product into the customer's hands early in the design cycle. The prototype is created using the easiest method to simulate functionality to the viewer. The customer comments on what is seen and the developers modify their design requirements. For example, when developing expert systems, models are almost never used. One of the driving rules is to show a prototype to the customer as soon as possible and afterwards throw it away! The purpose of building the prototype was to find out what the knowledge that needs to be represented is like, so that the appropriate tool can be selected to build the product. If, as is usually the case, a nonoptimal tool was used for the prototype, then the prototype is thrown away and a new one is developed using better tools and based on better understanding of the customer's requirements. Beware, though—often a key function displayed in the prototype is forgotten when the prototype is abandoned. Be certain to get all the information from the prototype [Maude and Willis, 1991]. The fault with this technique is that the requirements are not written down in detail. They are incorporated into the code as the code is written, and they can be overlooked or omitted when transferred to a new system.

## 164.3 When to Use Modeling and Prototyping

When should modeling versus prototyping be used? The key difference is the value of the

information obtained. Ultimately, the final product must be created. The prototype or model is used strictly to improve the final product. Costs associated with the prototype or model will be amortized over the number of units built. The major problem with models is the lack of confidence in the results. Sophisticated models are too complex for any single engineer to analyze. In fact, most models are now sold as proprietary software packages. The actual algorithms, precision, and number of iterations are rarely provided. The only way to validate the algorithm (not the model) is by repeated use and comparison to actual prototypes. It is easier to have confidence in prototypes. Actual parts can be measured and tested repeatedly, and the components and processes can be examined. Prototypes are used more often than models once the complexity of the device exceeds the ability of the computer to accurately reflect the part or process. During the initial design phases, models must be used because a prototype is meaningless until a concept has been more firmly defined. At the other extreme, modeling is of limited benefit to the factory until the configuration of the part is well known. A general rule is to build a model, then a prototype, then a production unit. Create even a simple mathematical model if possible so that the physics can be better understood. If the prototype is to be skipped, confidence in the model must be extremely high. If there is little confidence in the model, then a minimum of two or three prototype iterations will have to be done.

## Defining Terms

**Model:** An abstract representation of what the final system will be. It is often a mathematical or simplified representation of a product.

**Prototype:** A physical representation of a product built to verify a subset of the system's requirements.

**Stereolithography:** A prototype-manufacturing technique used to rapidly produce three-dimensional polymer models of parts using a CAD database.

### **Subhash H. Risbud**

*University of California, Davis*

One of the most critical aspects of engineering applications involves the selection, shaping, and processing of raw materials obtained either directly from the earth's crust or by special synthesis and purification methods. The history of successful cost competitive technologies and the development of modern societies is closely linked to one of two factors: (1) a new processing method for manufacturing a material with broad engineering utility, or (2) an altogether new discovery of a material with a composition that makes possible dramatically improved engineering properties. A good example of a processing method that can revolutionize engineering technologies is the now well-known discovery of zone refining and crystal growth of semiconductors, such as silicon and germanium, which are at the heart of the present day microelectronic industries. Similarly, the discovery of new materials is best exemplified by the finding in the mid-1980s that certain ceramics (mixtures of yttrium-barium-copper oxides)—long known to be ferroelectric—can actually lose all resistance to electric current and become superconductors at a relatively warm temperature of about 90 K. This discovery of a new material is likely to have a major impact in many fields of technology.

Engineers and scientists continue the rich historical trend of seeking new materials or an unusual method for shaping/processing a material. A particularly striking evidence of this is found in many of the current worldwide activities in the fast-growing field of nanotechnology. Thus, spectacular engineering properties are attainable by making extremely small structures that are many times smaller than the thickness of human hair. The principal goal is to synthesize nanometer-grained bulk materials or composite films in which at least one functional material has dimensions somewhere between 1 and 50 nm. Alternately, methods are being considered to carve out of bulk materials nanosize structures that promise to have a revolutionary impact on engineering and the physical and biological sciences. Examples of such materials and methods include the nanotechnology of making quantum wells and dots for laser optics, micromachined gears, ductile

ceramics, and molecular motors. This chapter intends to provide a "roadrunner's" view of methods for shaping and processing materials both by the well-established techniques (e.g., casting, welding, powder sintering) and the more recent evolving methods.

## 165.1 Processing Metals and Alloys

---

The major methods for making engineering parts from metallic alloys consist of casting from the molten (liquid) state, followed by cold or hot working of the casting by processes such as rolling, forging, drawing, extrusion, and spinning. Powders of metals and alloys are also made into shapes by pressing and sintering or hot pressing (HP) and hot isostatic pressing ("hipping"). Grinding, polishing, and welding are some of the final steps in the production of an engineering component. There is a growing interest in encouraging near-net-shape manufacturing methods for engineering components to minimize the wastage in machining and grinding operations. Powder metallurgy methods provide an important advantage in this regard.

### Casting Methods

**Casting** of liquid metals and alloys is one of the oldest and best-known processes for making ingots, or shapes in final form determined by the mold or die cavity in which the liquid is poured. The solidification of the liquid metal takes place after the melt is allowed to flow to all the areas of the mold. Shrinkage during solidification makes for a smaller casting size than the mold size, and this is accounted for in the design of the mold. Molds can vary from simple cavities to multipart molds clamped together and containing ceramic cores to create hollow spaces in some parts of the casting.

Sand mixed with clay is the best-known traditional mold material and is packed around a wooden pattern that is subsequently removed when the sand casting mold is ready for pouring of liquid metal. A small channel called a *gate* provides the liquid metal access to the mold cavity, while a riser column becomes the reservoir of liquid metal that feeds the shrinkage of the liquid metal during solidification. The sand-casting process is an inexpensive method for making a small number of parts; a range of ferrous and nonferrous alloys can be made by this method. The rough finish of sand cast parts usually requires further machining and grinding.

Die casting is performed by pouring liquid alloys into preshaped metal molds machined to good accuracy and final tolerance. Thus, the finished product is of good surface quality in die casting, and complex shapes can be made. Gravity die casting involves the flowing of the liquid metal under natural gravity conditions, whereas pressure die casting involves forcing the melt into the die under pressure. Centrifugal casting relies on a rotating mold to distribute the melt in the mold cavity by the action of centrifugal forces, a method specially suitable for making large-diameter metal pipes. Aluminum, zinc, copper and magnesium alloys are often made by die-casting methods. Because machined molds are required, die casting is more expensive than sand castings, although molds are reused, and thus the process is good for large-scale production. Investment casting or lost wax casting is specially used for alloys with high melting temperatures and when high dimensional accuracy and precision are needed. The high-melting metals attack the dies used in normal die casting and thus patterns are produced from wax using a metal mold. The wax

patterns are coated with a ceramic slurry and heated to melt the wax, whereupon a dense ceramic mold is created. Molten alloys are then forced into the ceramic mold cavity by use of pressure or by a centrifugal process. Complicated shapes (e.g., aerospace turbine blades) or shapes where fine detail is sought (e.g., figurines) are made by investment or lost wax casting methods.

#### IMPROVEMENT IN THE MANUFACTURE OF IRON AND STEEL

*Henry Bessemer*

*Patented July 25, 1865*

*#49,051*

To refine crude or so-called pig iron into steel, Englishman Bessemer found that jets of air or steam injected into molten iron would burn up the carbon impurities and decarbonize the iron until it became usable steel. The heat from the decarbonization also helped keep the metal molten so it could be poured into ingots for later processing into bars, plates and rods. His first patent for

making steel was granted in 1856 with many more including this one granted for improvements in the "blast furnace" process.

Patent #49,051 improved the process by causing air or steam to decarbonize the iron without the use of nozzles that could clog as in previous versions of the process. It also specified using partially evacuated airtight molds so the metal ingots would be less cellular, an undesirable defect. (©1993, DewRay Products, Inc. Used with permission.)

## Metal-Working Methods

Hot working of metal alloys is normally the next step in the shaping of the cast alloy into a component and is also used to induce some refinement of the grain structure of the material to obtain the necessary ductility or strength. In hot working the temperature is high enough that recrystallization occurs at a rate faster than work hardening due to deformation. Forging, rolling, and extrusion are some examples of hot-working processes.

Hot forging is a process of simply pressing the hot metal between two surfaces in open, closed, or flat-faced dies. This process is closest to the ancient art of the blacksmith, but modern manufacturing plants employ high-power hydraulic presses to deliver impact blows to achieve forging of large steel crankshafts, aerospace propellers, and so forth. Hot extrusion consists of taking a cylindrical billet from the cast ingot and placing the hot billet in a die of a slightly larger size. A piston or ram extrudes the hot metal through appropriately cut orifices or openings in the die. The process is akin to squeezing toothpaste out of a tube under pressure. Direct and inverted extrusion are the two most common variations of the extrusion process. Hot rolling is a popular method of reducing the cast ingots into billets, slabs, plates, or sheets by pressing the hot metal between rotating rollers. Four high-rolling mills consist of smaller-diameter work rolls backed by larger diameter backup rolls. Many other types of cluster mills also exist, including planetary mills and pendulum mills.

Cold working of metals and alloys has the advantage of producing a clean, smooth surface finish and a harder material. Cold rolling of aluminum foil or steel strips are some examples of products in everyday use that have surface finish that can vary from a standard bright finish to matte and plated finishes, depending on the application. Drawing is another cold-working process in which cylindrical rods can be drawn through a die to make wires or sheets of metal can be shaped into cup-shaped objects by deep drawing the sheet into a die by pressure from the punch. By clamping the sheet around the edges, the pressing operation can produce domestic cookware, automobile bodies, and a variety of cup-like shapes. Circular cross sections can be made by spinning a metal blank in a lathe while applying pressure to the blank with a tool to shape it. Explosive forming is a special process used for shaping large-area sheets of metal into contoured panels such as those needed in communication reflectors. The wave generated by detonation of an explosive charge is used to convert a sheet blank into the shape of the die. [Table 165.1](#) is a summary of the processes used with a listing of the advantages and limitations of each process.

**Table 165.1** Summary of Metal-Working Processes

Process	Economic Quantity	Typical Materials	Optimum Size
Sand casting	Small–large	No limit	1–100 kg
Die casting—gravity	Large	Al, Cu, Mg, Zn alloys	1–50 kg
Die casting—pressure	Large	Al, Cu, Mg, Zn alloys	50 g–5 kg
Centrifugal casting	Large	No limit	30 mm–1 m diam.
Investment casting	Small–large	No limit	50 g–50 kg
Closed-die forging	Large	No limit	3000 cm <sup>3</sup>
Hot extrusion	Large	No limit	500 mm diam.
Hot rolling	Large	No limit	—
Cold rolling	Large	No limit	—
Drawing	Small–large	Al, Cu, Zn, mild steel	3 mm–6 mm diam.
Spinning	One-off-large	Al, Cu, Zn, mild steel	6 mm–4.5 m diam.
Impact extrusion	Large	Al, Pb, Zn, mild steel	6 mm–100 mm diam.
Sintering	Large	Fe, W, bronze	80 g–4 kg
Machining	One-off-large	No limit	—

## Machining and Finishing

The cast, hot- or cold-worked metallic alloys are often subjected to some type of **machining** operation, which encompasses cutting, grinding, polishing, shearing, drilling, or other metal-removal methods. Chemical etching or polishing methods can also be used as finishing steps in the production of components from metals. Planing, turning, milling, and drilling are the main methods of removing chips from a metal part during the machining step. Surface finish and dimensional accuracy of the component are the main goals of machining. Cutting and grinding tools required in machining are usually made from hard metal (carbide) or ceramic materials; *machinability index* measures the ease with which a particular material can be machined with conventional methods. The higher the machinability index is, the easier it is to machine the metal or alloy. In addition to these methods, metal removal can also be achieved by ultrasonic abrasion, laser or electron beam cutting and drilling, electrodischarge or spark machining, arc milling, and chemical milling. Numerically controlled machining of high-precision components and sophisticated robotically controlled fabrication methods continue to be investigated and applied in the manufacture of engineering materials and components. Powder metallurgy methods are most suitable for directly converting powders of raw materials into finished shapes with little or no machining. This method, discussed later, has the greatest potential for near-net-shape manufacturing and is commonly used to consolidate metal, ceramic, and mixed composite powders.

## 165.2 Ceramics, Glasses, and Polymers

Nonmetallic materials such as ceramics, glasses, and polymeric organic materials require generally different methods for shaping and manufacturing than metals, although some common methods do

exist for all of these materials. Inorganic silicate glasses and polymer melts are processed by methods that take into account their viscoelastic properties. Ceramics are normally refractory and high-melting materials and thus require powder sintering, hot pressing or related methods for production.

## Powder Processing and Sintering

Powder sintering of metal alloy powders and ceramics is a versatile method of producing near-final shapes of a component. Ceramic powders are typically blended with solid or liquid additives, binders, and so forth, and the batched system is treated by a series of mixing, chemical dissolution, washing, de-airing, or filtration to produce a slurry, paste, or suspension of solid particles in a liquid, often referred to as the *slip*. Depending on the consistency (viscosity of the syrup) of the suspension, forming a shape is achieved by tape casting onto plastic sheets or by pouring the slip into a plaster mold, followed by drying to remove the residual liquids in the batch. The shaped porous ceramic at this stage is called a *green ceramic body*. Green machining, surface grinding, or application of coatings or glazes is done at this stage. The final step in the process is consolidation to a nearly pore-free solid by firing or sintering at a high temperature. The sintered microstructure is usually a multiphase combination of grains, secondary phases, and some degree of remaining porosity.

Another common way of sintering ceramics, and particularly metal powders, is by direct pressing of the powders with some solid additives (called *sintering aids*). The component shape is determined by a die cavity and the powders are cold pressed at relatively high pressures, followed by heat treatment to create the sintered microstructure. In a combination of these steps, pressure and heat can be applied simultaneously in hot pressing or hot isostatic pressing ("hipping"). In these methods the powder fills in the die cavity, and, as the pressure is applied by hydraulic rams, the die is heated simultaneously to consolidate the powder to a solid. The evolution of a microstructure from powders to dense ceramics with grains and grain boundaries is now a well-developed science-based technology. Thus, deliberate process control is needed, including awareness of atmospheres used in firing, particle size distribution, chemistry of additives, control over grain boundary mobility, and elimination of exaggerated grain growth. The recent development of fast sintering methods includes the use of sparks, microwaves, and plasmas to activate the surfaces of very fine powders (micrometers to as small as a few nanometer particles) and cause consolidation to occur in just a few minutes. Microwave sintering and plasma-activated sintering are examples of promising new methods on the horizon for very fast sintering to achieve small grain sizes and high-purity materials in both metallic and ceramic systems.

## Glasses and Glass-Ceramics

The manufacture of glasses from mixtures of silicon-dioxide (silica) and a number of other oxides (e.g., sodium, calcium, aluminum oxides) is based on melting the mixtures in a tank-like furnace to create a homogeneous bubble-free viscous melt. The composition of the glass is chosen such that, on cooling the melt during shaping, formation of the thermodynamically favored crystalline

material does not occur. To make glass plates or sheets (e.g., car windshields), the molten liquid is allowed to float onto the surface of a liquid bath of low-melting metal that is immiscible with the glass (the lighter glass floats on the higher-density metal melt). This float glass process is but one of a variety of ways of converting molten silicate liquids to glassy shapes. Viscous glass streaming out of a furnace can be trimmed into "gobs" that drop into a preshaped die while blowing air under pressure to force the mushy viscous gob into the final shape (e.g., a beer bottle). Molten glass compositions can also flow through bushings containing small orifices to create fiberglass materials or optical fibers. Optical fibers of high purity are also processed in drawing towers using preforms of carefully engineered clad-and-core compositions. Thousands of glass compositions with specific chemical ingredients are known for generating color, inducing a refractive index gradient, permitting selective transparency, or resisting weathering. The common window glass composition is based on a mixture of the oxides of sodium, calcium, and silicon and is popularly called soda-lime-silica glass.

Glass-ceramics are materials made by the heat treatment of a shaped piece of glass so as to allow the formation of copious amounts of small crystallites without changing the macroscopic dimensions of the object. The optical transparency of the glass changes to a translucent appearance typical of most glass-ceramics, best known in the form of domestic cookware sold under the trade name Corelle or Corningware, by Corning Glass Company. The glass-ceramic process is a useful method of obtaining fully dense ceramics from the glassy state and requires good control of the nucleating agents that are used to catalyze the crystallite formation in the glass-ceramic microstructure. The uniformity of the crystal grains in the structure and the small size are factors that give glass-ceramics the higher strength and better mechanical properties compared to glasses. The number of glass-ceramics available for use in engineering practice has grown enormously in the last 25 years; applications of glass-ceramics in electrical, magnetic, structural, and optical fields is becoming more common. Machinable glass-ceramics based on a mica-like crystalline phase have made it easier to shape glass-ceramics by conventional machine shop tools.

## HOW ALUMINUM IS MADE

### **Mining**

Bauxite, the ore rich in aluminum oxide from which most aluminum is produced, is found and mined widely around the world. Today, most bauxite mining locations are in the Caribbean area, Brazil, Australia, and Africa. Bauxite is the product of the chemical weathering of rocks containing aluminum silicates. The weathering process takes millions of years.

### **Refining**

Bauxite contains many impurities that are removed by heat and chemicals in the process known as refining. In this process, bauxite is ground, mixed with lime and caustic soda, pumped into high-pressure containers, and heated. The aluminum oxide is dissolved by the caustic soda, leaving undesired materials as a solid. The mixture is filtered to remove the solids and a crystallized material called hydrated alumina is made to drop out of the solution in a process known as seeding. The material is washed and heated to drive off water and produce a white

powder (resembling sugar) called alumina ( $\text{Al}_2\text{O}_3$ ), another name for aluminum oxide.

### **Smelting**

Aluminum is made from alumina powder by an electrolytic reduction process known as smelting. To get aluminum metal, alumina must be "reduced" to separate the aluminum and the oxygen. This is done by dissolving powdered alumina in a cryolite bath inside large, carbon-lined electrolytic reduction cells called pots. When a powerful direct electric current is passed through the bath, aluminum metal separates from the chemical solution. Heat generated by the electricity keeps the bath liquid, so more alumina can be added to make the process continuous. As liquid aluminum builds up on the bottom of the pots, it is siphoned off. The pots used in smelting are up to 15 feet wide and 40 feet long. They are electrically connected in series so that they all work at the same time. As many as 250 pots have been linked in a single potline. Most aluminum smelting plants have several potlines.

### **Fabricating**

Molten aluminum is removed from smelting pots in large containers called crucibles, then poured into furnaces for mixing with other metals in controlled amounts to make it stronger or to give it other special properties required for ultimate use. This process, known as alloying, takes place at temperatures of about 1220°F, the melting point of aluminum. In the furnace, aluminum is purified in a process called fluxing—done by forcing mixtures of gases through the hot metal. Impurities float to the surface and are removed. The aluminum then is poured into molds or cast directly into solid forms, called ingots, and worked.

**Direct chill casting**, a process invented by Alcoa, is the first step in many metal-working operations. It is done by rapid cooling with water to "freeze" molten aluminum as it passes through a mold. The result is aluminum of constant high quality, usually in rectangular or round ingots.

**Electromagnetic casting** is a moldless process that operates on the principle that current passing through a copper conductor induces an opposing current in molten aluminum. The current produces magnetic fields in both the aluminum and the copper conductor, which repel each other. Molten aluminum is thus suspended away from the copper conductor by a magnetic field. Without a mold, the hot ingot surface is in continuous contact with cooling water during solidification and a very smooth ingot surface is produced.

**Sheet and plate** ingots are often 30 feet long and weigh up to 20 tons. More operations are needed to roll sheet than the thicker plate.

**Foil** is made from aluminum sheets passed between rolls until very thin. Some is rolled to under .0002 of an inch thick, about the thickness of human hair.

**Forging**, the ancient art of pressing metal into shapes, is still widely used. Heated ingots are in some cases hammered to make precision and high-strength aluminum parts. The largest forgings are made on presses with forces up to 50,000 tons.

**Drawn bar and rod** products are pulled through similarly shaped dies, each progressively smaller in diameter. When rod is drawn to less than 3/8 of an inch, it is called wire. Wire is stranded into cable to carry electricity.

**Extrusions** are made by heating ingots until they can be easily shaped with a powerful press. An extrusion ingot (called a billet) is pushed through a shaped die just as toothpaste is squeezed from a tube. Over 100,000 shapes—some simple, some complex—have been extruded in

aluminum.

***Drawn tube*** products are pulled through a die that controls outside measurements while an insert called a mandrel controls inside measurements. This drawing process is repeated until the tube is the desired size. (Courtesy of the Aluminum Company of America.)

## Sol-Gel Methods

**Sol-gel processes** make it possible to use organic-polymeric synthesis methods to produce ceramics and glasses at relatively low temperatures. The major advantage of sol-gel techniques is that all the chemicals needed in a glass or ceramic can be blended into a solution to create a "sol" at close to room temperature. This avoids the high-temperature processing normally used in making a ceramic or a glass. The sol is then made to gel by appropriate hydrolysis reactions, and the gel is then fired into a monolithic body or made into coatings, powders, films, and so forth. The calcination and sintering steps remove water and vestiges of organic bonds to form an inorganic ceramic product. Not all ceramics can be made by sol-gel techniques—not because of any fundamental limitations, but due mainly to the lack of well-developed connections between a suitable starting precursor and the synthesis protocol to make the final ceramic or glass. For making bulk monoliths or coatings and films, the use of drying control agents in sol-gel processing is crucial to attain crack-free objects.

## Polymer Processing

The forming of organic polymeric materials essentially consists of making powders or granules of the requisite blend of polymers with additives such as carbon, chalk, and paper pulp. In the next step the granules are heated to soften the polymer mixture, and the soft material is viscoelastically shaped into the final component. The processing methods mainly involve extruding, injection molding, casting, and calendering. The particular process used depends on the quantity, size, and form in which the polymer object is desired (e.g., sheets of plastic or bulk rods). Thermosetting polymers go through an irreversible chemical change upon heating and they are mostly made by molding or casting. Examples include thermosetting resins such as urea, melamine or phenol formaldehydes, and polyesters. Thermoplastic polymers are processible by repeated softening as long as the temperature is not too high to cause decomposition and charring. Ease of flow makes these attractive for processing by injection molding and extrusion methods. Examples include polycarbonate, polyethylene, polystyrene, polyamide (nylon), and polyvinyl chloride (PVC). Inclusion of gas gives rise to foamed plastics such as polystyrene foam (for thermal insulation), whereas polymers are reinforced by fibers (typically glass fibers) to form composites with better stiffness and strength. The glass fiber polymer composites are shaped by injection molding and are useful in environments where moisture-resistant, high-fracture toughness materials are needed. Continuous sheets of plastic are made from PVC or polyethylene polymers by calendering. This process consists of feeding the heated polymer granules or powder through a set of heated rollers. The first roller converts the granules to a sheet that is subsequently reduced to the appropriate

thickness and surface finish. Laminates and coatings of polymers are formed by pressing, casting, and roll-coating technologies. Large polymer pieces such as boat hulls are put together manually by pasting several layers of gum-fiber–reinforced polyester. For a large number of parts (automobile bodies, etc.), vacuum forming of PVC or polypropylene-type polymers is the desired method. A comparison of some polymer-processing methods is shown in [Table 165.2](#)

**Table 165.2** Comparison of Various Polymer-Processing Methods

Process	Production Rate	Material Type	Optimum Size
Extrusion	Fast	Th, plastic	Few mm-1.8 m
		Th, set	
Blow molding	Fast	Th, plastic	$10^{-6}$ -2 m <sup>3</sup>
Injection molding	Fast	Th, set	15 g-6 kg
Compression molding	Fast	Th, set	Few mm-0.4 m
Transfer molding	Fast	Th, set	Few mm-0.4 m
Layup techniques	Slow	Th, set and filler	0.01-400 m <sup>2</sup>
Rotational molding	Medium	Th, plastic	$10^{-3}$ -30 m <sup>3</sup>
Thermoforming	Fast	Th, plastic	$10^{-3}$ -20 m <sup>2</sup>

## 165.3 Joining of Materials

Temporary joints between the shaped finished components made from several materials are easily achieved by mechanical means such as nuts, bolts, pins, and so forth. Permanent joining of two materials requires physical or chemical changes at the joining surfaces. For joining metals and alloys, welding, brazing, and soldering are the most common methods. Fusion welding consists of melting a part of the metal at the joint interface and allowing the joint to form by flow of the liquid metal, usually with another filler metal. When the same process is assisted by compressive forces applied by clamping the two pieces, the process is called *pressure welding*. Brazing and soldering use a lower-melting filler metal alloy to join the components. The parent pieces do not undergo melting and the liquid filler acts as the glue that makes the joint. The heat required to cause melting in the welding process classifies the process. Thus, in arc welding, heat is provided by creating an electric arc between electrodes often in the presence of a shielding atmosphere. Gas welding is performed using a gas mixture fuel to create a high-temperature flame that is targeted at the joining interface. The most popular gas-welding device is the oxyacetylene welding torch commonly seen in metal-working shops. Thermite welding is a well-known process for joining large sections in remote locations where gas or electric welding are difficult to perform. The thermite process relies on the exothermic heat generated by the reaction of iron oxide with aluminum. The molten product of the exothermic reaction is brought in contact with the joining interface and causes local melting of the parent pieces, followed by cooling, to form the weld. Electron and laser beam welding are some of the modern methods for joining metals and ceramics. Other methods include electrosag welding, friction welding, and explosive welding, which is made possible by a transient wave

generated by detonating a charge of explosives.

The joining of ceramics and glasses involves some methods common to metals and some that are specific to preparing glass-metal seals. Ceramic joining and bulk ceramic processing are closely related; the main joining methods consist of adhesive bonding, brazing with metals or silicates, diffusion bonding, fusion welding, and cementitious bonding. Brazing of metals to ceramics has attracted much recent attention because of its applications in heat engines, where high-temperature ceramic components (e.g., silicon nitride based) are in use. Thus, metallic alloys based on Ti, Zr, and Fe-Ni-Co are used to braze silicon nitride parts designed for high-temperature service. Thermal expansion mismatch between joining materials is an important criterion in the choice of those materials. Studies of glass-metal, ceramic-metal, ceramic-ceramic, and ceramic-polymer interfaces have led to a sophisticated understanding of joints, coatings, and enamels used in ceramic, electronic, and thermal engineering applications.

## Defining Terms

**Casting:** The shaping of a metal alloy into a solid piece by pouring liquid metal into the cavity inside a sand mold.

**Machining:** Final steps in the manufacture of a component; may include cutting, polishing, and grinding operations.

**Metal working:** Process steps to shape the cast material into components by cold or hot work. Examples of processes include rolling, forging, extrusion, and drawing.

**Powder processing:** The conversion of powdered material into a solid piece by cold pressing and heating (sintering) or simultaneous heating and pressure application (hot pressing).

**Sol-gel process:** The use of organic or organometallic solutions to make the component into a bulk piece or coating at lower temperatures than in conventional melting and casting. Used for oxide ceramics and glasses at present.

## Machine Tools and Processes

---

### 166.1 Economic Impact

### 166.2 Types of Machine Tools

### 166.3 Control of Machine Tools

Interpolation • Feedback Control

### 166.4 Machine Tool Accuracy

#### Yung C. Shin

*Purdue University*

Machine tools are the machinery used to process various materials in order to get desired shapes and properties. Machine tools typically consist of a base structure, which supports various components and provides overall rigidity; kinematic mechanisms and actuators, which generate necessary motions of the tools and tables; and various feedback sensors. Machine tools are often used in conjunction with jigs and fixtures, which would hold the part in position, and processing tools. An example of a machine tool used in material removal processing is shown in [Fig. 166.1](#).

The first generation of modern machine tools was introduced during the industrial revolution in the 18th century with the invention of steam engines. Machine tools opened an era of automation by providing the means to replace human work with mechanical work. In the early days automation with machine tools was performed using various kinematic mechanisms, but it evolved into programmable automation with the use of computer numerical control. Today, many machine tools are operated with electrical or hydraulic power and controlled by a computer.

The major application of automation using machine tools in the early years was in transfer lines. Many special-purpose machines were grouped together with a part-moving system, such as a conveyor, providing the transfer of parts from one machine to another. A specific operation was performed on each station, and the part was moved to the next station until the finished product was obtained. Recently, however, **flexible automation** has been actively pursued to cope with continuous and rapid change of product designs and cycles. In such systems, several numerically controlled machines are clustered together to perform a variety of jobs. Programs are used, instead of inflexible mechanisms, to control the machines, so that the system can easily adapt to different job requirements.

### 166.1 Economic Impact

---

In most industrialized countries manufacturing contributes to about 20 to 30% of the nation's GNP. Since most manufacturing processes are performed with machine tools, the production and consumption of machine tools play a significant role in the nation's economy. Machine tool companies in the U.S. have a direct employment of about 350 000 people. If the surrounding ancillary industries are included—such as the tooling industry, material-handling industry, and sensors and controller manufacturers—the total employment would double that figure. More importantly, the machine tool industry affects a much larger user community.

**Figure 166.1** An example of machine tools.

## 166.2 Types of Machine Tools

Various manufacturing processes led to development of a variety of machine tools. Therefore, machine tools can be categorized by manufacturing processes. Manufacturing processes can be grouped into four main categories: casting, forming, material removing, and joining.

*Casting machines* are used to generate various unfinished or finished parts of defined shapes from shapeless materials. Casting is typically performed under high temperatures with molten material. The material in liquid state is poured into a mold or a die, which has the shape of the final part, and is subsequently solidified. Examples of casting processes entail sand casting, centrifugal casting, die casting, and continuous casting. No processing tools are used on this type of machine, and high accuracy is not usually required. Casting is usually followed by forming or machining processes in order to attain a final shape or to improve the dimensional accuracy.

*Forming machines* are used to change the shape of materials in the solid state. During the process, no significant change of volume or weight in the material occurs, but the mechanical properties are altered due to the large amount of bulk deformation and high stresses. Forming processes are performed at either high or low temperature. The required force and power are usually large. Examples of forming machine tools include presses; forging machines; rolling mills; and stamping, drawing, extrusion, and bending machines.

*Material removal processes* are used to obtain an accurate shape of a part that has been obtained by casting or forming processes. During the material removal process, the volume as well as the shape is changed. Machine tools used for material removal processes often require the highest accuracy. Typical processes under this category include turning, drilling, milling, boring, grinding, and so forth. Material removal processes have been used mostly for metals but have recently found new applications in nonmetallic materials such as ceramics and composites.

Machine tools for material removal processes are designed to provide multiaxis motions. They usually consist of a table used for mounting a workpiece, a spindle to hold tools, and a motor and gears to provide various speeds and feeds. In order to obtain a precision motion, axes are often controlled by microprocessor-based computer numerical controllers.

In addition to the processes already mentioned, many nontraditional machining processes are commonly used these days. Nontraditional machining processes include any that use another energy source with or without mechanical power. Typical nontraditional machining processes are electrodischarge machining (EDM), electrochemical grinding, laser machining, and electron-beam machining. These processes utilize either electric or heat energy to remove the material.

*Joining* is an operation to assemble components. Examples are welding, soldering, adhesion, and riveting. These processes are usually performed at the final stage to fabricate a product from various finished components. The types of machine tools in this category are friction-welding, arc-welding, electron-beam–welding, and laser-welding machines. In addition, robots are

## 166.3 Control of Machine Tools

---

In the early days machine tools were controlled automatically by means of mechanical systems such as cams, gears, and levers, which provided repetitive or sequential motions of machine tools. These mechanical devices shifted the operator's role from turning wheels or moving levers to supervising overall operation.

Later, hydraulic control replaced the mechanical control systems. Hydraulic systems provided more precise actions with higher power. The hydraulic control later combined with electronic switches were able to generate much more complex operations than mechanical control systems, but were eventually replaced by electronic controls.

*Numerically controlled* (NC) machines were developed to achieve automatic operation of machine tools with a program. The NC machine was first conceived by John Parson in 1948, and the first prototype was introduced by Massachusetts Institute of Technology (MIT) in 1952. In early NC machines, electric relays were grouped and hard-wired so that users could generate a complex sequence of operations. In NC machines, programs to generate commands for the sequences of operations were stored into punched tapes, which were subsequently read into a computer which interpreted the program and generated pulses to drive mechanisms.

In the beginning mainframes were used as computers to process the data. However, microprocessors and magnetic media replaced numerical control in the 1970s and opened the era of computer numerical controllers (CNC). Instead of being connected to the mainframe computer and sequentially controlled, CNC machines were designed with individual microprocessor-based controllers. CNC machines are usually equipped with a tool magazine, which holds multiple tools. These machines can perform many different operations on a single machine with automatic tool change and hence are called *machining centers*.

Computer programs used to operate the CNC machines are called *part programs*, which contain a sequence of commands. The commands used in a part program include preparatory G codes and M codes defining miscellaneous functions, as well as specific codes such as S, F, T, or X codes. The G codes are universally used regardless of the type of CNC and are defined in both ISO (International Standards Organization) and EIA (Electronic Industry Association) standards (RS-273-A). Some examples of these codes are shown in [Table 166.1](#). With NC or CNC machine tools, part programs can be generated at a remote site. The English-like languages, such as Automatic Programming Tool (APT), are commonly used for the ease of generating part programs. Nowadays, various computer-aided manufacturing (CAM) packages provide means to graphically generate part programs from design drawings created by computer-aided design (CAD) software. The part programs generated with CAM software must be postprocessed into the format of the specific CNC to be used and downloaded to the machine, where it can be edited if necessary.

**Table 166.1** Examples of G and M Codes for Part Programs

G00	Point-to-point positioning	M03	Spindle rotation, CW
G01	Linear interpolation	M04	Spindle rotation, CCW
G02	Circular interpolation, CW	M05	Spindle stop
G03	Circular interpolation, CCW	M06	Tool change
G06	Spline interpolation	M08	Coolant No. 1 on
G17	xy-plane selection	M09	Coolant stop
G41	Tool radius compensation, left		

## Interpolation

Most CNC controllers have the capability of performing various types of interpolation. The simplest type is point-to-point interpolation. This scheme, in which beginning and final positions are of greatest importance, is usually used for rapid movement of tools or workpieces. The second type is the straight-line interpolation, which is used to generate a motion following a straight line with a specified speed. Accurate positioning and maintenance of a constant speed are required. The most complicated type of interpolation is contouring. Trajectory commands for contouring are typically generated using circular or cubic spline functions. [Figure 166.2](#) shows the graphical illustration of these interpolations.

**Figure 166.2** Illustration of interpolations.

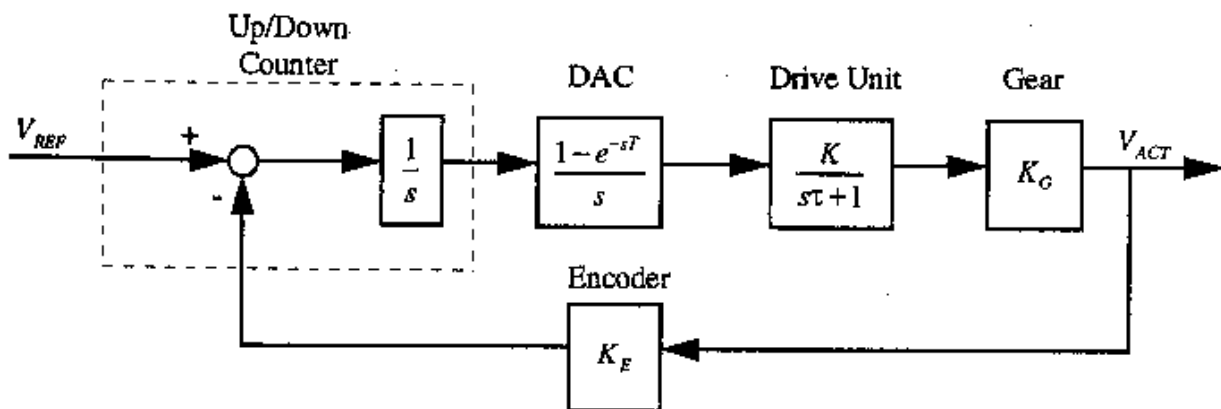

## Feedback Control

The generated commands are sent to the actuators of each axis to provide the necessary motion of the pertinent component in either open-loop or closed-loop configuration. In early CNC machines, stepper motors were often used as actuators, but their usage is at present limited to inexpensive, small machine tools. Either DC (direct current) or AC (alternating current) servomotors are popularly used for modern machine tools with feedback control. [Figure 166.3](#) shows the open-loop control system with a stepper motor, whereas [Fig. 166.4](#) depicts the closed-loop configuration.

**Figure 166.3** Open-loop control system with stepper motors.

**Figure 166.4** Closed-loop control system with stepper motors.

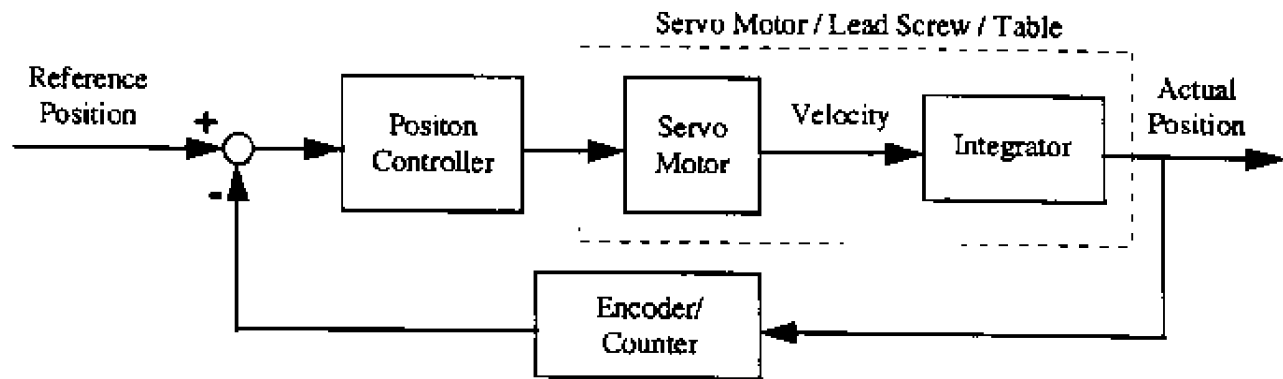

Early NC systems used a control scheme based on pulse reference and counting. In this scheme, positional reference commands are input to the system as a series of pulses, and the position feedback is obtained through an encoder. The command pulses are generated by the NC controller, with each pulse corresponding to a fixed **basic length unit** (BLU), which determines the system's accuracy. The frequency of the pulses determines the velocity of the axis, and positional accuracy is achieved by comparing the feedback pulses with the input pulse through the up-down counter.

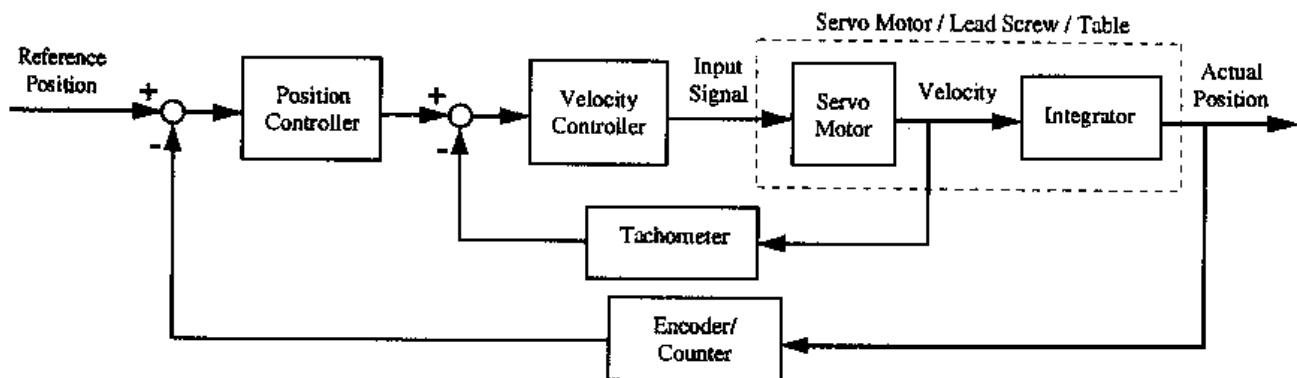

In more recent CNC systems, command generation and control are performed digitally using a digital controller with servomotors. Proportional-integral-derivative (PID) controllers are most popularly used as feedback controllers with either single- or double-feedback loops. An example of a position control system with a proportional controller is shown in Fig. 166.5. The more advanced system shown in Fig. 166.6 has two feedback loops, which perform velocity control in the inner loop and position tracking in the outer loop. The most common method uses a proportional type

for the position control and a PI controller for the velocity loop. These controllers are designed for the nominal operating condition of the machine.

**Figure 166.5** Digital position control system.

**Figure 166.6** Digital control system with position and velocity feedback.

Recently, adaptive control (AC) has opened a new era for machine tool control. Adaptive control provides the machine tool with the ability to adapt itself to the dynamic changes of the process condition to maintain optimum performance. Without adaptive control, operating conditions might have to be chosen too conservatively to avoid failure, thereby resulting in the loss of productivity. In addition, adaptive control can improve the accuracy of an existing machine, particularly in contouring. Adaptive control is particularly important for the realization of untended operation in the factory of the future.

## 166.4 Machine Tool Accuracy

The standard of accuracy has been increasing steadily over the last few decades. With the advent

of high-precision machine tool technology and measurement techniques, manufacturers can presently attain accuracy that was almost impossible to achieve a few decades ago. For example, machining accuracy of 5 to 10  $\mu\text{m}$  from regular machine tools and 0.1  $\mu\text{m}$  from precision machine tools is routinely achieved. It is projected that the accuracy will improve about tenfold every two decades.

The accuracy of a part produced by a machine tool is influenced by many factors, such as

- Machine tool accuracy
- Deflection or distortion of the part due to load or temperature
- Process operating condition
- Tool wear
- Environmental disturbances

Among these causes, the machine tool accuracy plays a very important role.

The machine tool error is defined as the deviation from the desired or planned path of the movement between the tool and the workpiece. Machine tool errors are typically grouped into geometric and kinematic errors. *Geometric error* includes positional inaccuracies of the individual link and the errors in the shape of the machine tool components. *Kinematic errors* are those occurring in coordinated movement of multiple machine elements. Therefore, kinematic errors depend on the machine's kinematic configuration and functional movements.

Machine tool errors stem from many sources, including imperfect fabrication of elements; assembly errors; friction; and errors associated with control, temperature variation, weight, and so forth. Depending on the source of error, various testing techniques must be adopted to evaluate the accuracy. Typical test methods include cutting tests, geometrical tests of moving elements, and master part tract tests. The details of test procedures are described in [Hocken, 1980; NMTBA, 1972; ANSI/ASME, 1985]. In addition, machine tool accuracy varies over time depending on the environment, operating history, and maintenance and hence can deteriorate significantly [Shin *et al.*, 1991]. Therefore, it is necessary to test the accuracy of the machine tools periodically and recalibrate the axes.

Machine tool error is divided into two categories: repeatable (deterministic) and nonrepeatable (random) errors. Typical measurements of positional errors are shown in Fig. 166.7. Due to the backlash and friction, errors often exhibit hysteresis if the measurements are performed in both directions. Generally, accuracy is defined as the worst possible error at a particular position and is represented in terms of a deterministic value defined as the mean deviation from the target position and the probabilistic distribution of random variation. Mathematically, positional accuracy is defined as

$$\varepsilon(x, y, z) = \max(|\mu + 3\sigma|, |\mu - 3\sigma|)$$

where  $\mu$  is the mean positional accuracy and  $\sigma$  is the variance of the random part. The nonrepeatable portion is used to specify the repeatability. Typically three sigma (variation) values are used to determine the repeatability.

**Figure 166.7** Presentation of errors of a machine tool axis moving in two directions.

## Defining Terms

**Basic length unit:** Smallest resolution attainable in positioning.

**Flexible automation:** Automation used to produce a variety of parts without converting the hardware set up.

The science of **ergonomics** originated in 1857 when Wojciech Jastrzebowski of Poland defined the term by combining two Greek words: *ergon* (work) + *nomos* (laws). This new science signified then the human work, play, thinking, and devotion as reflected in the manner of optimizing the use of four distinct human characteristics: (1) motor (physical), (2) sensory (aesthetic), (3) mental (intellectual), and (4) spiritual or moral [Karwowski, 1991]. The term *ergonomics* was independently reinvented by K. F. H. Murrell in 1949. Contemporary **human factors** (the parallel term for this new scientific discipline adopted in the U.S.), "discovers and applies information about human behavior, abilities, limitations, and other characteristics to the design of tools, machines, systems, tasks, jobs, and environments for productive, safe, comfortable, and effective human use" [Sanders and McCormick, 1993]. For example, human factors/ergonomics deals with a broad scope of problems relevant to the design and evaluation of work systems, consumer products, and working environments, whereas human-machine interactions affect human performance and product usability. The wide scope of issues addressed by ergonomics is presented in Table 167.1.

*Human factors design and engineering* aims to optimize the design and functioning of human-machine systems with respect to complex characteristics of people and the relationships between system users, machines, and outside environments. According to the Board of Certification in Professional Ergonomics (BCPE) a practitioner of ergonomics is a person who (1) has a mastery of a body of ergonomics knowledge, (2) has a command of the methodologies used by ergonomists in applying that knowledge to the design of a product, system, job, or environment, and (3) has applied his or her knowledge in the analysis, design testing, and evaluation of products, systems and environments. The areas of current practice in the field can be best described by examining the focus of technical groups of the Human Factors and Ergonomics Society, as illustrated in [Table 167.2](#).

**Table 167.2** Subject Interests of Technical Groups of the Human Factors and Ergonomics Society

	Technical Group	Description/Areas of Concerns
I.	Aerospace systems	Applications of human factors to the development, design, operation, and maintenance of human-machine systems in aviation and space environments (both civilian and military).
II.	Aging	Human factors applications appropriate to meeting the emerging needs of older people and special populations in a wide variety of life settings.
III.	Communications	All aspects of human-to-human communication, with an emphasis on communication mediated by telecommunications technology, including multimedia and collaborative communications, information services, and interactive broadband applications.

		Design and evaluation of both enabling technologies and infrastructure technologies in education, medicine, business productivity, and personal quality of life.
IV.	Computer systems	Human factors aspects of (1) interactive computer systems, especially user interface design issues; (2) the data-processing environment, including personnel selection, training, and procedures; and (3) software development.
V.	Consumer products	Development of consumer products that are useful, usable, safe, and desirable. Application of the principles and methods of human factors, consumer research, and industrial design to ensure market success.
VI.	Educators' professional	Education and training of human factors and ergonomics specialists in academia, industry, and government. Focus on both degree-oriented and continuing education needs of those seeking to increase their knowledge and or skills in this area, accreditation of graduate human factors programs, and professional certification.
VII.	Environmental design	Human factors aspects of the constructed physical environment, including architectural and interior design aspects of home, office, and industrial settings. Promotion of the use of human factors principles in environmental design.
VIII.	Forensics professional	Application of human factors knowledge and technique to "standards of care" and accountability established within legislative, regulatory, and judicial systems. The emphasis on providing a scientific basis to issues being interpreted by legal theory.
IX.	Industrial ergonomics	Application of ergonomics data and principles for improving safety, productivity, and quality of work in industry. Concentration on service and manufacturing processes, operations, and environments.
X.	Medical systems and functionally impaired populations	All aspects of the application of human factors principles and techniques toward the improvement of medical systems, medical devices, and the quality of life for functionally impaired user populations.
XI.	Organizational design	Improving productivity and the quality of life by an integration of psychosocial, cultural, and technological factors and with user interface factors (performance, acceptance, needs, limitations) in design of jobs, workstations, and related management systems.
XII.	Personality and individual differences in humanperformance	The range of personality and individual difference variables that are believed to mediate performance.
XIII.	Safety	Research and applications concerning human factors in safety and injury control in all settings and attendant populations, including transportation, industry, military, office, public building, recreation, and home improvements.
XIV.	System development	Concerned with research and exchange of information for integrating human factors into the development of systems. Integration of human factors activities into system development

		processes in order to provide systems that meet user requirements.
XV.	Test and evaluation	A forum for test and evaluation practitioners and developers from all areas of human factors and ergonomics. Concerned with methodologies and techniques that have been developed in their respective areas.
XVI.	Training	Fosters information and interchange among people interested in the fields of training and training research.
XVII.	Visual performance	The relationship between vision and human performance, including (1) the nature, content, and quantification of visual information and the context in which it is displayed; (2) the physics and psychophysics of information display; (3) perceptual and cognitive representation and interpretation of displayed information; (4) assessment of workload using visual tasks; and (5) actions and behaviors that are consequences of visually displayed information.

---

## 167.1 The Concept of Human-Machine Systems

---

A human-machine system can be broadly defined as "an organization of man and woman and the machines they operate and maintain in order to perform assigned jobs that implement the purpose for which the system was developed" [Meister, 1987]. The human functioning in such a system can be described in terms of perception, information processing, decision making, memory, attention, feedback, and human response processes. Furthermore, the human work taxonomy can be used to describe five distinct levels of human functioning, ranging from primarily physical tasks to cognitive tasks [Karwowski, 1992]. These basic but universal human activities are (1) tasks that produce force (primarily muscular work), (2) tasks of continuously coordinating sensory-monitor functions (e.g., assembling or tracking tasks), (3) tasks of converting information into motor actions (e.g., inspection tasks), (4) tasks of converting information into output information (e.g., required control tasks), and (5) tasks of producing information (primarily creative work).

Any task in a human-machine system requires processing of information that is gathered based on perceived and interpreted relationships between system elements. The processed information may need to be stored by either a human or a machine for later use. One of the important concepts for ergonomic design of human-machine systems is the paradigm of the stimulus-response compatibility [Wickens, 1987]. This paradigm relates to the physical relationship (compatibility) between a set of stimuli and a set of responses, as this relationship affects the speed of human response. The spatial relations between arrangements of signals and response devices in human-machine systems with respect to direction of movement and adjustments are often ambiguous, with a high degree of uncertainty regarding the effects of intended control actions. It should be noted that the information displayed to the human operator can be arranged along a continuum that defines the degree to which that information is spatial-analog (i.e., information about relative locations, transformations or continuous motion), linguistic-symbolic, or verbal (i.e., a set of instructions, alphanumeric codes, directions, or logical operations). The scope of ergonomic factors that need to be considered in design, testing, and evaluation of any

human-machine system is shown in [Table 167.3](#) in the form of an exemplary ergonomic checklist.

**Table 167.3** Examples of Factors to Be Used in the Ergonomics Checklists

**I. Anthropometric, biomechanical, and physiological factors**

1. Are the differences in human body size accounted for by the design?
2. Have the right anthropometric tables been used for specific populations?
3. Are the body joints close to neutral positions?
4. Is the manual work performed close to the body?
5. Are there any forward-bending or twisted trunk postures involved?
6. Are sudden movements and force exertion present?
7. Is there a variation in worker postures and movements?
8. Is the duration of any continuous muscular effort limited?
9. Are the breaks of sufficient length and spread over the duration of the task?
10. Is the energy consumption for each manual task limited?

**II. Factors related to posture (sitting and standing)**

1. Is sitting/standing alternated with standing/sitting and walking?
2. Is the work height dependent on the task?
3. Is the height of the work table adjustable?
4. Are the height of the seat and backrest of the chair adjustable?
5. Is the number of chair adjustment possibilities limited?
6. Have good seating instructions been provided?
7. Is a footrest used where the work height is fixed?
8. Has the work above shoulder or with hands behind the body been avoided?
9. Are excessive reaches avoided?
10. Is there enough room for the legs and feet?
11. Is there a sloping work surface for reading tasks?
12. Have the combined sit-stand workplaces been introduced?
13. Are handles of tools bent to allow for working with the straight wrists?

**III. Factors related to manual materials handling** (lifting, carrying, pushing and pulling loads)

1. Have tasks involving manual displacement of loads been limited?
2. Have optimum lifting conditions been achieved?
3. Is anybody required to lift more than 23 kg?
4. Have lifting tasks been assessed using the NIOSH (1991) method?
5. Are handgrips fitted to the loads to be lifted?
6. Is more than one person involved in lifting or carrying tasks?
7. Are there mechanical aids for lifting or carrying available and used?
8. Is the weight of the load carried limited according to the recognized guidelines?
9. Is the load held as close to the body as possible?
10. Are pulling and pushing forces limited?
11. Are trolleys fitted with appropriate handles and handgrips?

**IV. Factors related to the design of tasks and jobs**

1. Does the job consist of more than one task?
2. Has a decision been made about allocating tasks between people and machines?
3. Do workers performing the tasks contribute to problem solving?
5. Are the difficult and easy tasks performed interchangeably?
6. Can workers decide independently on how the tasks are carried out?
7. Are there sufficient possibilities for communication between workers?
8. Is there sufficient information provided to control the assigned tasks?

9. Can the group take part in management decisions?
10. Are the shift workers given enough opportunities to recover?

## **V. Factors related to information and control tasks**

### Information

1. Has an appropriate method of displaying information been selected?
2. Is the information presentation as simple as possible?
3. Has the potential confusion between characters been avoided?
4. Has the correct character/letter size been chosen?
5. Have texts with capital letters only been avoided?
6. Have familiar typefaces been chosen?
7. Is the text/background contrast good?
8. Are the diagrams easy to understand?
9. Have the pictograms been properly used?
10. Are sound signals reserved for warning purposes?

### Controls

1. Is the sense of touch used for feedback from controls?
2. Are differences between controls distinguishable by touch?
3. Is the location of controls consistent and is sufficient spacing provided?
4. Have the requirements for the control-display compatibility been considered?
5. Is the type of cursor control suitable for the intended task?
6. Is the direction of control movements consistent with human expectations?
7. Are the control objectives clear from the position of the controls?
8. Are controls within easy reach of female workers?
9. Are labels or symbols identifying controls properly used?
10. Is the use of color in controls design limited?

### Human-computer interaction

1. Is the human-computer dialogue suitable for the intended task?
2. Is the dialogue self-descriptive and easy to control by the user?
3. Does the dialogue conform to the expectations on the part of the user?
4. Is the dialogue error-tolerant and suitable for user learning?
5. Has command language been restricted to experienced users?
6. Have detailed menus been used for users with little knowledge and experience?
7. Is the type of help menu fitted to the level of user's ability?
8. Has the QWERTY layout been selected for the keyboard?
9. Has a logical layout been chosen for the numerical keypad?
10. Is the number of function keys limited?
11. Have the limitations of speech in human-computer dialogue been considered?
12. Are touch screens used to facilitate operation by inexperienced users?

## **VI. Environmental factors**

### Noise and vibration

1. Is the noise level at work below 80 dBA?
2. Is there an adequate separation between workers and source of noise?
3. Is the ceiling used for noise absorption?
4. Are the acoustic screens used?
5. Are hearing conservation measures fitted to the user?
6. Is personal monitoring to noise/vibration used?
7. Are the sources of uncomfortable and damaging body vibration recognized?
8. Is the vibration problem being solved at the source?
9. Are machines regularly maintained?
10. Is the transmission of vibration prevented?

#### Illumination

1. Is the light intensity for normal activities in the range of 200 to 800 lux?
2. Are large brightness differences in the visual field avoided?
3. Are the brightness differences between task area, close surroundings, and wider surroundings limited?
4. Is the information easily legible?
5. Is ambient lighting combined with localized lighting?
6. Are light sources properly screened?
7. Can the light reflections, shadows, or flicker from the fluorescent tubes be prevented?

#### Climate

1. Are workers able to control the climate themselves?
2. Is the air temperature suited to the physical demands of the task?
3. Is the air prevented from becoming either too dry or too humid?
4. Are draughts prevented?
5. Are the materials/surfaces that have to be touched neither too cold nor too hot?
6. Are the physical demands of the task adjusted to the external climate?
7. Are undesirable hot and cold radiation prevented?
8. Is the time spent in hot or cold environments limited?
9. Is special clothing used when spending long periods in hot or cold environments?

#### Chemical substances

1. Is the concentration of recognized hazardous chemical substances in the air subject to continuous monitoring and limitation?
2. Is the exposure to carcinogenic substances avoided or limited?
3. Does the labeling on packages of chemicals provide information on the nature of any hazard due to their contents?
4. Can the source of chemical hazards be removed, isolated, or their releases from the source reduced?
5. Are there adequate exhaust and ventilation systems in use?
6. Are protective equipment and clothing—including gas and dust masks for emergencies and gloves—available at any time if necessary?

## 167.2 Ergonomics in Industry

---

The knowledge and expertise offered by ergonomics as applied to industrial environments can be used to (1) provide engineering guidelines regarding redesign of tools, machines, and work layouts, (2) evaluate the demands placed on the workers by the current jobs, (3) simulate alternative work methods and determine potential for reducing physical job demands if new methods are implemented, and (4) provide a basis for employee selection and placement procedures.

The basic foundations for ergonomics design are based on two components of industrial ergonomics: engineering anthropometry and biomechanics. **Occupational biomechanics** can be defined as the application of mechanics to the study of the human body in motion or at rest [Chaffin and Anderson, 1993]. Occupational biomechanics provides the criteria for application of anthropometric data to the problems of workplace design. **Engineering anthropometry** is an

empirical science branching from physical anthropology that (1) deals with physical measurements for the human body (such as body size, form (shape), and body composition), including, for example, the location and distribution of center of mass, weights, body links, or range of joint motions, and (2) applies these measures to develop specific engineering design requirements.

The recommendations for workplace design with respect to anthropometric criteria can be established by the principle of *design for the extreme*, also known as the *method of limits* [Pheasant, 1986]. The basic idea behind this concept is to establish specific boundary conditions (percentile value of the relevant human characteristic), which, if satisfied, will also accommodate the rest of the expected user population. The main anthropometric criteria for workplace design are clearance, reach, and posture. Typically, clearance problems involve the design of space needed for the legs or safe passageways around and between equipment. If the clearance problems are disregarded, they may lead to poor working postures and hazardous work layouts. Consideration of clearance requires designing for the largest user, typically by adapting the 95th percentile values of the relevant characteristics for male workers. Typical reach problems in industry include consideration of the location of controls and accessibility of control panels in the workplace. The procedure for solving the reach problems is usually based upon the fifth percentile value of the relevant characteristic for female workers (smaller members of the population). When anthropometric requirements of the workplace are not met, biomechanical stresses that manifest themselves in postural discomfort, lower-back pain, and overexertion injury are likely to occur.

## 167.3 The Role of Ergonomics in Prevention of Occupational Musculoskeletal Injury

---

Lack of attention to ergonomic design principles at work and its consequences have been linked to occupational musculoskeletal injuries and disorders. Musculoskeletal work-related injuries, such as cumulative trauma to the upper extremity and lower-back disorders (LBDs), affect several million workers each year, with total costs exceeding \$100 billion annually. For example, the upper-extremity **cumulative trauma disorders (CTDs)** account today for about 11% of all occupational injuries reported in the U.S. and have resulted in a prevalence of work-related disability in a wide range of occupations.

The dramatic increase of musculoskeletal disorders over the last 10 to 15 years can be linked to several factors, including the increased production rates leading to thousands of repetitive movements every day, widespread use of computer keyboards, higher percentage of women and older workers in the workforce, and better record keeping of employers as a result of a crackdown on industry reporting procedures by the Occupational Safety and Health Administration (OSHA). Other factors include greater employee awareness of these disorders and their relation to the working conditions, as well as a marked shift in the social policy regarding the recognition of compensation for work-related disorders. Given the epidemic proportions of the reported work-related musculoskeletal injuries, the federal government increases its efforts to introduce minimum standards and regulations aimed to reduce the frequency and severity of these disorders. For more information about these efforts, see Waters *et al.* [1993]; for NIOSH guidelines for manual lifting, see the ANSI [1994] draft document on control of CTDs.

The current state of knowledge about CTDs indicate that the chronic muscle, tendon, and nerve disorders may have multiple work-related and non-work-related causes. Therefore, CTDs are not classified as occupational diseases but rather as *work-related disorders*, where a number of factors may contribute significantly to the disorder, including work environment and human performance at work. The frequently cited risk factors of CTDs are (1) repetitive exertions; (2) posture—shoulder (elbow above mid-torso reaching down and behind), forearm (inward or outward rotation with a bent wrist), wrist (palmar flexion or full extensions), and hand (pinching); (3) mechanical stress concentrations over the base of palm, on the palmar surface of the fingers, and on the sides of the fingers; (4) vibration; (5) cold; and (6) use of gloves [Putz-Anderson, 1988]. A risk factor is defined here as an attribute or exposure that increases the probability of the disease or disorder. Cumulative trauma disorders at work are typically associated with repetitive manual tasks that impose repeated stresses to the upper body, that is, the muscles, tendons, ligaments, nerves, tissues, and neurovascular structures. For example, the three main types of disorders to the arm are (1) tendon disorders (e.g., tendonitis), (2) nerve disorders (e.g., carpal tunnel syndrome), and (3) neurovascular disorders (e.g., thoracic outlet syndrome or vibration-Raynaud's syndrome).

From the occupational safety and health perspective, the current state of ergonomics knowledge allows for management of CTDs in order to minimize human suffering, potential for disability, and the related worker's compensation costs. Ergonomics can help to (1) identify working conditions under which the CTDs might occur, (2) develop engineering design measures aimed at elimination or reduction of the known job risk factors, and (3) identify the affected worker population and target it for early medical and work intervention efforts. The ergonomic intervention should allow management to (1) perform a thorough job analysis to determine the nature of specific problems, (2) evaluate and select the most appropriate intervention(s), (3) develop and apply conservative treatment (implement the intervention), on a limited scale if possible, (4) monitor progress, and (5) adjust or refine the intervention as needed.

Most of the current guidelines for control of the CTDs at work aim to (1) reduce the extent of movements at the joints, (2) reduce excessive force levels, and (3) reduce exposure to highly repetitive and stereotyped movements. Workplace design to prevent the onset of CTDs should be directed toward fulfilling the following recommendations: (1) permit several different working postures; (2) place controls, tools, and materials between waist and shoulder heights for ease of reach and operation; (3) use jigs and fixtures for holding purposes; (4) resequence jobs to reduce the repetition; (5) automate highly repetitive operations; (6) allow self-pacing of work whenever feasible; and (7) allow frequent (voluntary and mandatory) rest breaks. For example, some of the common methods to control the wrist posture are (1) altering the geometry of tool or controls (e.g., bending the tool or handle), (2) changing the location/positioning of the part, or (3) changing the position of the worker in relation to the work object. In order to control the extent of force required to perform a task, one can (1) reduce the force required through tool and fixture redesign, (2) distribute the application of the force, or (3) increase the mechanical advantage of the (muscle) lever system.

## 167.4 Fitting the Work Environment to the Workers

---

Ergonomic job redesign focuses on fitting the jobs and tasks to capabilities of workers—for example, "designing out" unnatural postures at work, reducing excessive strength requirements, improving work layout, introducing appropriate designs of hand tools, and addressing the problem of work/rest requirements. As widely recognized in Europe, ergonomics must be seen as a vital component of the value-adding activities of the company. Even in strictly financial terms, the costs of an ergonomics management program will be far outweighed by the costs of not having one. A company must be prepared to accept a participative culture and to utilize participative techniques. The ergonomics-related problems and consequent intervention should go beyond engineering solutions and must include design for manufacturability, total quality management, and work organization alongside workplace redesign or worker training.

An important component of the management efforts to control musculoskeletal disorders in industry is the development of a well-structured and comprehensive ergonomics program. The basic components of such a program should include the following: (1) health and risk factor surveillance, (2) job analysis and improvement, (3) medical management, (4) training, and (5) program evaluation. Such a program must include participation of all levels of management; medical, safety, and health personnel; labor unions; engineering; facility planners; and workers.

The expected benefits of ergonomically designed jobs, equipment, products, and workplaces include the improved quality and productivity with reductions in errors, enhanced safety and health performance, heightened employee morale, and accommodation of people with disabilities to meet the requirements of the Americans with Disabilities Act and affirmative action. However, the recommendations offered by ergonomics can be successfully implemented in practice only with full understanding of the production processes, plant layouts, quality requirements, and total commitment from all management levels and workers in the company. Furthermore, these efforts can only be effective through participatory cooperation between management and labor through development of in-plant ergonomics committees and programs. Ergonomics must be treated at the same level of attention and significance as other business functions of the plant—for example, the quality management control—and should be accepted as a cost of doing business, rather than an add-on activity calling for action only when the problems arise.

### Defining Terms

**Cumulative trauma disorders (CTDs):** CTDs at work are typically associated with repetitive manual tasks with forceful exertions, performed with fixed body postures that deviate from neutral, such as those at assembly lines and those using hand tools, computer keyboards, mice, and other devices. These tasks impose repeated stresses to the soft tissues of the arm, shoulder, and back, including the muscles, tendons, ligaments, nerve tissues, and neurovascular structures, which may lead to tendon and/or joint inflammation, discomfort, pain, and potential work disability.

**Engineering anthropometry:** An empirical science branching from physical anthropology that deals with physical measurements for the human body—such as body size, form (shape), and body composition—and application of such measures to the design problems.

**Ergonomics/human factors:** The scientific discipline concerned with the application of the relevant information about human behavior, abilities, limitations, and other characteristics to

the design, testing, and evaluation of tools, machines, systems, tasks, jobs, and environments for productive, safe, comfortable, and effective human use.

**Occupational biomechanics:** The application of mechanics to the study of the human body in motion or at rest, focusing on the physical interaction of workers with their tools, machines, and materials in order to optimize human performance and minimize the risk of musculoskeletal disorders.

## 168.1 Pressure

---

Pressure ( $P$ ) can be defined as a force ( $F$ ) acting on a given area ( $A$ );  $P = F/A$ . It is measured using metric (SI) units, pascals (Pa), or English units, pounds per square inch (psi). Pressure can also be indicated in absolute (abs) or gage (g) (as measured with a gage) units. Relationships between metric and English units of measure are as follows:

- 100 kPa = 1 bar = 14.7 psia  $\approx$  1 atmosphere (atm).
- 100 kPa gage (or 100 kPa) = 14.7 psig (or 14.7 psi).
- 1 MPa abs = 147 psia.

- 1 MPa gage (or 1 MPa) = 147 psig (or 147 psi).

These units can be used when measuring seven kinds of pressure:

- *Absolute pressure*: sum of atmospheric and gage pressures.
- *Atmospheric pressure*: ambient pressure at local elevations. The atmospheric pressure at sea level is approximately 100 kPa or 14.7 psia.
- *Burst pressure*: theoretical or actual pressure at which a vessel/component will fail.
- *Gage pressure*: pressure above atmospheric pressure as measured by a gage.
- *Maximum allowable working pressure (MAWP)*: maximum pressure at which component is safe to operate. MAWP is the maximum permissible setting for relief devices. Service, rated, design, and working pressure (WP) are the same as MAWP.
- *Maximum operating pressure (MOP)*: maximum pressure for continuous operation. MOP should be 10 to 20% below MAWP.
- *Pressure test*: a test to ensure that a vessel or system will not fail or permanently deform and will operate reliably at a specified pressure.

## Temperature

Temperature ( $T$ ) is the intensity of heat in a substance and may be measured on the graduated scale of a thermometer. It is usually measured in degrees Fahrenheit ( $^{\circ}\text{F}$ ) or degrees Celsius ( $^{\circ}\text{C}$ ). The two absolute scales are: Rankine (R) and Kelvin (K) (see [Table 168.1](#)).

**Table 168.1** Comparison of Temperature Scales<sup>1,2</sup>

Criterion	Fahrenheit ( $^{\circ}\text{F}$ )	Rankine abs (R)	Celsius or Centigrade ( $^{\circ}\text{C}$ )	Kelvin abs (K)
Water boils	212	672	100.0	373.0
Water freezes	32	492	0.0	273.0
Zero $^{\circ}\text{F}$	0	460	-17.7	255.3
Absolute zero	-460	0	-273.0	0.0

<sup>1</sup>Conversion factors:  $^{\circ}\text{F} = \frac{9}{5}^{\circ}\text{C} + 32$ ;  $^{\circ}\text{C} = \frac{5}{9} (^{\circ}\text{F} - 32)$ ;  $\text{R} = ^{\circ}\text{F} + 460$ ;  $\text{K} = ^{\circ}\text{C} + 273$ .

<sup>2</sup>Use absolute temperatures, either Rankine or Kelvin, in all calculations involving the ideal gas law, except when temperature is constant.

*Source*: This work was performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under contract N. W-7405-Eng-48.

## Volume

Volume ( $V$ ) refers to a space occupied in three dimensions. It is generally measured in cubic meters ( $\text{m}^3$ ), cubic centimeters ( $\text{cm}^3$ ), cubic inches ( $\text{in}^3$ ), or cubic feet ( $\text{ft}^3$ ). Volume may also be measured in units of liters (L) or gallons (gal).

## Basic Pressure Equations

### General Gas Law

The general (or ideal) gas law is the basic equation that relates pressure, volume, and temperature of a gas. It is expressed mathematically as

$$\frac{PV}{T} = \text{constant} \quad (168.1)$$

where

$P$  = pressure in kilopascals absolute (kPa abs) or pounds per square inch absolute (psia).  
(Add atmospheric pressure of 100 kPa or 15 psia to gage pressure.)

$V$  = volume in any convenient cubic unit such as liters, cubic feet,  
etc.

$T$  = temperature in absolute units of Rankine or Kelvin.

When the conditions of a gas system change, they do so according to this general gas law, at least where moderate pressures are concerned. At higher pressures ( $P > 200$  atm) gases do not obey the general gas law exactly; this problem is discussed later.

The following checklist will assist in solving general gas law problems:

1. Sketch the problem and mark all conditions.
2. List initial and final values of  $P$ ,  $V$ , and  $T$ . Use absolute units for  $P$  and  $T$ .
3. Write the general gas law for initial and final conditions. Cross out conditions that remain constant.
4. Substitute known values and solve for unknowns.
5. Convert your answer if it is in units different from those given in the problem.

The general gas law expressed for initial (subscript 1) and final (subscript 2) conditions is

$$\frac{P_1 V_1}{T_1} = \frac{P_2 V_2}{T_2} \quad (168.2)$$

Any one of these quantities can be solved for by simply cross-multiplying. Following is an example to show how easily the general gas law can be applied and how much can be determined about the behavior of gases.

**Example.** A cylinder of dry nitrogen is received from a vendor. The temperature of the nitrogen is 70°F, and the pressure within the cylinder is 2250 psig. An employee inadvertently stores the cylinder too close to a radiator so that within 8 hours the nitrogen is heated to 180°F. What is the new pressure within the cylinder?

Initial	Final
$P_1 = 2250 \text{ psig} = 2265 \text{ psia}$	$P_2 = (\text{find})$
$V_1 = V_2 = \text{constant}$	$V_2 = V_1 = \text{constant}$
$T_1 = 70^\circ\text{F} + 460^\circ = 530 \text{ R}$	$T_2 = 180^\circ\text{F} + 460^\circ = 640 \text{ R}$

$$\frac{P_1 \cancel{V_1}}{T_1} = \frac{P_2 \cancel{V_2}}{T_2} \quad \text{cross-multiplying,} \quad P_2 = \frac{P_1 T_2}{T_1} \quad (168.3)$$

$$P_2 = \frac{2265 \times 640}{530} = 2735 \text{ psia} = 2720 \text{ psig}$$

### Pascal's Law

According to Pascal's law, pressure exerted on a confined fluid will act in all directions with equal force.

$$\text{Pressure} = \frac{\text{Force}}{\text{Area}} \quad \text{or} \quad \text{Force} = \text{Pressure} \times \text{Area} \quad (168.4)$$

**Example.** Find the force on the end of a cylinder (see [Fig. 168.1](#)).

$$F = AP \quad \text{or} \quad F = 450 \text{ in.}^2 \times 90 \text{ lb/in.}^2 = 40\,500 \text{ lb of force}$$

**Figure 168.1** Example problem: force on the end of a cylinder.

### Safety Factor

The ratio of the calculated failure pressure (or actual failure pressure if known) to the MAWP is

the safety factor.

$$SF = \frac{\text{Burst pressure}}{\text{MAWP}} \quad (168.5)$$

A safety factor related to a value other than the failure pressure should be so identified with an appropriate subscript, for example,  $SF_y$  for a safety factor based on the yield strength or  $SF_u$  for a safety factor based on the ultimate strength of the material.

### Stored Energy in a Pressurized System

Gas confined under high pressure is like a hungry tiger in a cage. If it should suddenly escape in a populated area, someone would probably be injured. When a gas-pressure vessel fails, it propels jagged vessel fragments in all directions. The energy of the gas, assuming isentropic expansion, is expressed as

$$U_{\text{gas}} = \frac{P_1 V}{k - 1} \left[ 1 - \left( \frac{P_2}{P_1} \right)^{(k-1)/k} \right] \quad (168.6)$$

where

$U_{\text{gas}}$  = stored energy

$P_1$  = container pressure

$P_2$  = atmospheric pressure

$V$  = volume of the pressure vessel

$k = c_p/c_v = 1.41$  for  $N_2$ ,  $H_2$ ,  $O_2$ , and air, and 1.66 for He [see [Baumeister, 1958, chap. 4](#)]

$c_p$  = specific heat at constant pressure

$c_v$  = specific heat at constant volume

This expression as written will yield an energy value in joules if pressure and volume units are in megapascals (MPa) and cubic centimeters (cc), respectively.

A liquid confined under high pressure is also a potential safety hazard. However, for systems of comparable volume and pressure, the amount of stored energy in the liquid case will be considerably less than that contained in the gas because liquids are essentially noncompressible. The energy involved in the sudden failure of a liquid-filled vessel may be conservatively determined from

$$U_{\text{liq}} = \frac{1}{2} \left( \frac{P_1^2 V}{B} \right) \quad (168.7)$$

where  $B$  is the liquid bulk modulus. Some typical bulk moduli ( $B$ ) are 300 000 psi for water, 225 000 psi for oil, and 630 000 psi for glycerin.

An additional and significant potential source of released energy for confined gases is chemical reactions, for example, hydrogen and oxygen. For these special situations a separate analysis

addressing any potential chemical energy release should also be made [see [Baumeister, 1958, chap. 4](#)].

## Basic Design Equations (Internally Pressurized Vessels)

The following equations, when properly applied, give stresses that can be expected to exist in a design—longitudinal or axial stress ( $s_1$ ), circumferential or hoop stress ( $s_2$ ), and radial stress ( $s_3$ ) (see [Fig. 168.2](#)). These stresses must be compared to those permitted for the vessel material after application of the appropriate safety factor.

**Figure 168.2** Stress in thin cylinders.

### Thin Cylinders

A cylinder (or any vessel) is said to be "thin" when its thickness ( $t$ ) and internal radius ( $r_i$ ) satisfy the following relationship:

$$\frac{t}{r_i} \leq 0.1 \quad (168.8)$$

The following stresses exist in a thin cylinder:

$$s_1 = \frac{P}{2} \times \frac{r_i}{t}, \quad s_2 = P \times \frac{r_i}{t}, \quad s_3 = -P \quad (168.9)$$

Given  $P = 800$  psig,  $r_i = 5$  in.,  $t = 0.25$ , then  $s_1 = 8000$  psi,  $s_2 = 16\,000$  psi, and  $s_3 = -800$  psi.

### Thin Spheres

The following stresses exist in a thin sphere (see [Fig. 168.3](#)):

$$s_1 = s_2, \quad s_2 = \frac{P}{2} \times \frac{r_i}{t}, \quad s_3 = -P \quad (168.10)$$

Given:

$$\frac{t}{r_i} = 0.05 (\leq 0.1), \quad \frac{r_i}{t} = 20, \quad s_1 = s_2 \quad (168.11)$$

Then  $s_1 = 800/2 \times 20 = 8000$  psi and  $s_3 = -800$  psi. *Note that the hoop stress of a thin sphere is half the hoop stress of a corresponding thin cylinder.*

**Figure 168.3** Stress in thin spheres.

### Thick Cylinders (Roark)

A cylinder or sphere is "thick" when its dimensions satisfy the following relationship [Roark, 1989]:

$$\frac{t}{r_i} > 0.1 \quad (168.12)$$

The following stresses exist in a thick cylinder (see Fig. 168.4):

$$\begin{aligned} S_1 &= P \frac{r_i^2}{(r_o^2 - r_i^2)}, & S_2 &= P \frac{r_o^2 + r_i^2}{(r_o^2 - r_i^2)} \text{ (max. inner surface),} \\ S_3 &= -P \text{ (max. inner surface)} \end{aligned} \quad (168.13)$$

**Figure 168.4** Stress in thick cylinders.

### Thick Cylinders (Lamé)

Compare Roark's equation with that of Lamé [Baumeister, 1958, chap. 5]. Use the same vessel and conditions as above, with hoop stress maximum at the inner surface.

$$S_1 = P \frac{R^2 + 1}{R^2 - 1}, \quad R = \frac{r_o}{r_i} \quad (168.14)$$

Note that the Lamé equation agrees with Roark's. Actually, it is the same equation.

### Thick Spheres

Figure 168.5 shows the stress relationship in thick spheres, where  $t/r_i > 0.1$  .

$$\begin{aligned} s_1 \text{ (max. inner surface)} &= s_2, \\ s_2 &= \frac{P(r_o^3 + 2r_i^3)}{2E(r_o^3 - r_i^3)} \quad \text{where } E \text{ is the joint efficiency} \quad (168.15) \\ s_3 \text{ (max. inner surface)} &= -P \end{aligned}$$

Figure 168.5 Stresses in thick spheres.

## 168.2 The Vacuum Environment

As a practical definition, any environment in which the pressure is lower than atmospheric may be referred to as a vacuum. It is useful to express this subatmospheric pressure condition in units which reference zero pressure. Atmospheric pressure is approximately equal to 760 torr, 101 300 Pa, or 14.7 psi. Table 168.2 provides conversion factors for some basic units.

Table 168.2 Conversion Factors for Selected Pressure Units Used in Vacuum Technology

	Pa	torr	atm	mbar	psi
Pa	1	0.0075	$9.78 \cdot 10^{-6}$	0.01	$1.45 \cdot 10^{-4}$
torr	133	1	$1.32 \cdot 10^{-3}$	1.333	0.0193
atm	$1.01 \cdot 10^5$	760	1	1013	14.7
mbar	100	0.75	$9.87 \cdot 10^{-4}$	1	0.0145
psi	6890	51.71	$6.80 \cdot 10^{-2}$	68.9	1

The *ideal gas law* is generally valid when pressure is below atmospheric.

$$PV = nRT \quad (168.16)$$

where

$P$  = pressure [atm]

$V$  = volume [liters]

$n$  = amount of material [**moles**]

$R$  = gas law constant [0.082 liter-atm/K-mole]

$T$  = temperature [K]

The rate at which molecules strike a surface of unit area per unit time is referred to as the *impingement rate* and is given by

$$I = 3.5 \times 10^{22} \left( \frac{P}{MW \times T} \right) \quad (168.17)$$

where

$P$  = pressure [torr]

$MW$  = molecular weight [g/mole]

$T$  = temperature [K]

The distance, on average, that a molecule can travel without colliding with another molecule is the *mean free path* and is given by

$$\lambda = \frac{1}{\sqrt{2}\pi d_o^2 n} \quad (168.18)$$

where

$\lambda$  = mean free path [m]

$d_o$  = molecular diameter [m]

$n$  = gas density (molecules per cubic meter) [ $\text{m}^{-3}$ ]

The *average velocity* of molecules in the gas phase is a function of the molecular weight of the gaseous species and the average temperature.

$$\overline{V} = 145.5 \sqrt{\frac{T}{MW}} \quad (168.19)$$

where  $V$  = average velocity [m/s].

## Methods for Measuring Subatmospheric Pressures

A wide variety of gages are used in vacuum applications. Gage selection is based upon the vacuum system operating pressure range, the presence of corrosive gases, the requirement for computer interface, and unit cost.

Subatmospheric pressure gages ([Table 168.3](#)) which infer pressure (gas density) from measurement of some physical property of the rarefied gas, have the unfortunate characteristic of

being gas species-sensitive. Most commercial gages are calibrated for nitrogen; calibration curves for other gas species are available. Other factors which influence the readings of pressure gages used in vacuum technology include: location of the gage on the system, cleanliness of the gage elements, orientation of the gage, and environment of the gage (temperature, stray electric and magnetic fields). Gage readings are typically accurate to  $\pm 10\%$  of the reported value.

**Table 168.3** Subatmospheric Pressure Gages

Type	Principle of Operation	Range [torr]
U tube manometer	Liquid surface displacement	1–760
Bourdon tube	Solid surface displacement	1–760
McLeod gage	Liquid surface displacement	$10^{-4}$ – $10^{-1}$
Diaphragm gage	Solid surface displacement	$10^{-1}$ –760
Capacitance manometer	Solid surface displacement	$10^{-3}$ –760
Thermocouple gage	Thermal conductivity of gas	$10^{-3}$ –1
Piraini gage	Thermal conductivity of gas	$10^{-3}$ –760
Spinning rotor gage	Viscosity of gas	$10^{-7}$ – $10^{-2}$
Hot cathode ion gage	Gas ionization cross section	$10^{-12}$ – $10^{-4}$

## Methods for Reducing Pressure in a Vacuum Vessel

Vacuum pumps (Table 168.4) generally fall into one of two categories: primary (roughing) pumps and secondary (high-vacuum) pumps. Primary pumps are used to evacuate a vacuum vessel from atmospheric pressure to a pressure of about 10 mtorr. Secondary pumps typically operate in the pressure range of from  $10^{-10}$  to  $10^{-3}$  torr.

**Table 168.4** Vacuum Pumps

Type	Principle of Operation	Range [torr]
Rotary vane	Positive gas displacement	$10^{-2}$ –760
Rotary piston	Positive gas displacement	$10^{-2}$ –760
Cryo-sorption	Gas capture	$10^{-3}$ –760
Oil vapor diffusion	Momentum transfer	$10^{-9}$ – $10^{-3}$
Turbomolecular	Momentum transfer	$10^{-9}$ – $10^{-3}$
Sputter-ion	Gas capture	$10^{-10}$ – $10^{-3}$
He cryogenic	Gas capture	$10^{-10}$ – $10^{-3}$

Pump speed curves such as those presented in Figs. 168.6 and 168.7 are generally supplied by the pump manufacturer and reflect optimal performance for pumping air.

**Figure 168.6** Pump speed curve typical of a two-stage oil-sealed rotary vane pump.

**Figure 168.7** Pump speed curve typical of a fractionating oil-vapor diffusion pump equipped with a liquid nitrogen cold trap.

## Vacuum System Design

The following relationships provide a first-order method for calculating **conductances**, delivered pump speed, and time to achieve a specified pressure. These relationships assume that conductance elements are of circular cross section and have smooth internal surfaces, and that the gas being pumped is air.

The conductance of tubes and orifices is a function of the flow mode (see Fig. 168.8), which in turn is determined by the average pressure and the conductance element inside diameter. Flow modes may be determined by the following method:

$$D\bar{P} > 0.18 \Rightarrow \text{turbulent flow}$$

$$D\bar{P} < 0.004 \Rightarrow \text{molecular flow} \quad (168.20)$$

where

$D$  = tube inside diameter [in.]

$\bar{P}$  = average pressure [torr]

$$C = \frac{3000\bar{P}D^4 + 80D^3}{L} \quad (168.21)$$

where

$C$  = conductance [L/s]

$D$  = tube inside diameter [in.]

$\bar{P}$  = average pressure [torr]

$L$  = tube length [in.]

**Figure 168.8** Conductance as a function of pressure for a 1.0" I.D. tube 10 feet long.

For conductance elements connected in series, the total conductance is given by

$$\frac{1}{C_{\text{tot}}} = \sum_{i=1}^n \frac{1}{C_i} \quad (168.22)$$

where

$C_{\text{tot}}$  = total conductance [L/s]

$C_i$  = conductance of  $i$ th tube [L/s]

Manufacturers of vacuum components (valves, traps, etc.) generally publish the conductance of the unit in the molecular flow regime. If this information is unavailable, the maximum conductance of a valve or trap may be estimated using the formula for aperture conductance in molecular flow:

$$C_m^{\text{ap}} = 75A \quad (168.23)$$

where

$C_m^{\text{ap}}$  = molecular flow conductance [L/s]

$A$  = area of aperture [ $\text{in.}^2$ ]

The effect of conductance on the pump speed delivered to a vessel may be evaluated using the following relationship:

$$\frac{1}{S_t} = \frac{1}{C_{\text{tot}}} + \frac{1}{S_p} \quad (168.24)$$

where

$S_t$  = delivered pump speed [L/s]

$S_p$  = speed measured at pump inlet [L/s]

The amount of time required to evacuate a vessel using a primary pump is given by:

$$t = \frac{V}{S_t} \ln \left( \frac{P_1}{P_2} \right) \quad (168.25)$$

where

$t$  = time to pump from  $P_1$  to  $P_2$  [s]

$V$  = volume of vessel [L]

$S_t$  = delivered pump speed [L/s]

$P_1$  = initial pressure [torr]

$P_2$  = final pressure [torr]

The lowest pressure (ultimate pressure) a vacuum system can attain is a function of the total gas load [which is the algebraic sum of gas loads due to leaks, **outgassing** (see [Table 168.5](#)),

permeation, and process gas] and the pumping speed of the secondary pump.

$$Q_{\text{tot}} = S_i P_u \quad (168.26)$$

where

$Q_{\text{tot}}$  = total gas load [torr-L/s]

$P_u$  = ultimate pressure [torr]

**Table 168.5** Outgassing Data for Materials Used in Vacuum Vessels [O'Hanlon, 1989]

Treatment		$q$ [W/m <sup>2</sup> ]	$q$ [T · 1/s·cm <sup>2</sup> ]
Metals			
Aluminum	15 h at 250°C	$5.3 \cdot 10^{-10}$	$3.98 \cdot 10^{-13}$
Aluminum	100 h at 100°C	$5.3 \cdot 10^{-11}$	$3.98 \cdot 10^{-14}$
6061 aluminum	Glow discharge and 200°C bake	$1.3 \cdot 10^{-11}$	$9.75 \cdot 10^{-15}$
Copper	20 h at 100°C	$1.46 \cdot 10^{-9}$	$1.10 \cdot 10^{-12}$
304 stainless steel	30 h at 250°C	$4.0 \cdot 10^{-9}$	$3.00 \cdot 10^{-12}$
316L stainless steel	2 h at 800°C	$4.6 \cdot 10^{-10}$	$3.45 \cdot 10^{-13}$
U15C stainless steel	3 h at 1000°C and 25 h at 360°C	$2.1 \cdot 10^{-11}$	$1.58 \cdot 10^{-14}$
Glasses			
Pyrex glass	Fresh	$9.8 \cdot 10^{-7}$	$7.35 \cdot 10^{-9}$

Elastomers			
Viton-A	Fresh	$1.52 \cdot 10^{-3}$	$1.14 \cdot 10^{-6}$
Neoprene	—	$4.0 \cdot 10^{-2}$	$3.00 \cdot 10^{-5}$

## Defining Terms

**Conductance:** Mass throughput divided by the pressure drop across a tube.

**Mole:** Amount of material,  $6.02\text{E}+23$  particles; 1 mole of carbon weighs 12 grams.

**Outgassing:** Evolution of gas from a solid or liquid in a vacuum environment.

### 169.1 Liquid Transport Systems

#### 169.2 Heat Transfer

**R. Paul Singh**

*University of California, Davis*

The food industry relies on a wide range of unit operations to manufacture a myriad of processed foods. In order to design food processes, a practitioner in the food industry uses fundamental principles of chemistry, microbiology, and engineering. During the last 30 years, the food engineering discipline has evolved to encompass several aspects of food processing. The diversity of processes typically employed in a food processing plant is illustrated in [Fig. 169.1](#). Typical food processes may include sorting and size reduction, transport of liquid foods in pipes, heat transfer processes carried out using heat exchangers, separation processes using membranes, simultaneous heat and mass transfer processes important in drying, and processes that may involve a phase change such as freezing. A food engineer uses the concepts common to the fields of chemical, mechanical, civil, and electrical engineering in addition to food sciences to design engineering systems that interact with foods. When foods are used as raw materials they offer unique challenges. Perhaps the most important concern in food processing is the variability in the raw material. To achieve consistency in the final quality of a processed food, the processes must be carefully designed to minimize variations caused by processing. In this chapter, some of the unique engineering issues encountered in food processing will be presented. For more details on the engineering design of food processing systems, the reader is referred to books by Singh and Heldman [1993], Toledo [1991], Brennan *et al.* [1990], Heldman and Singh [1981], Loncin and Merson [1979], and Charm [1978].

## 169.1 Liquid Transport Systems

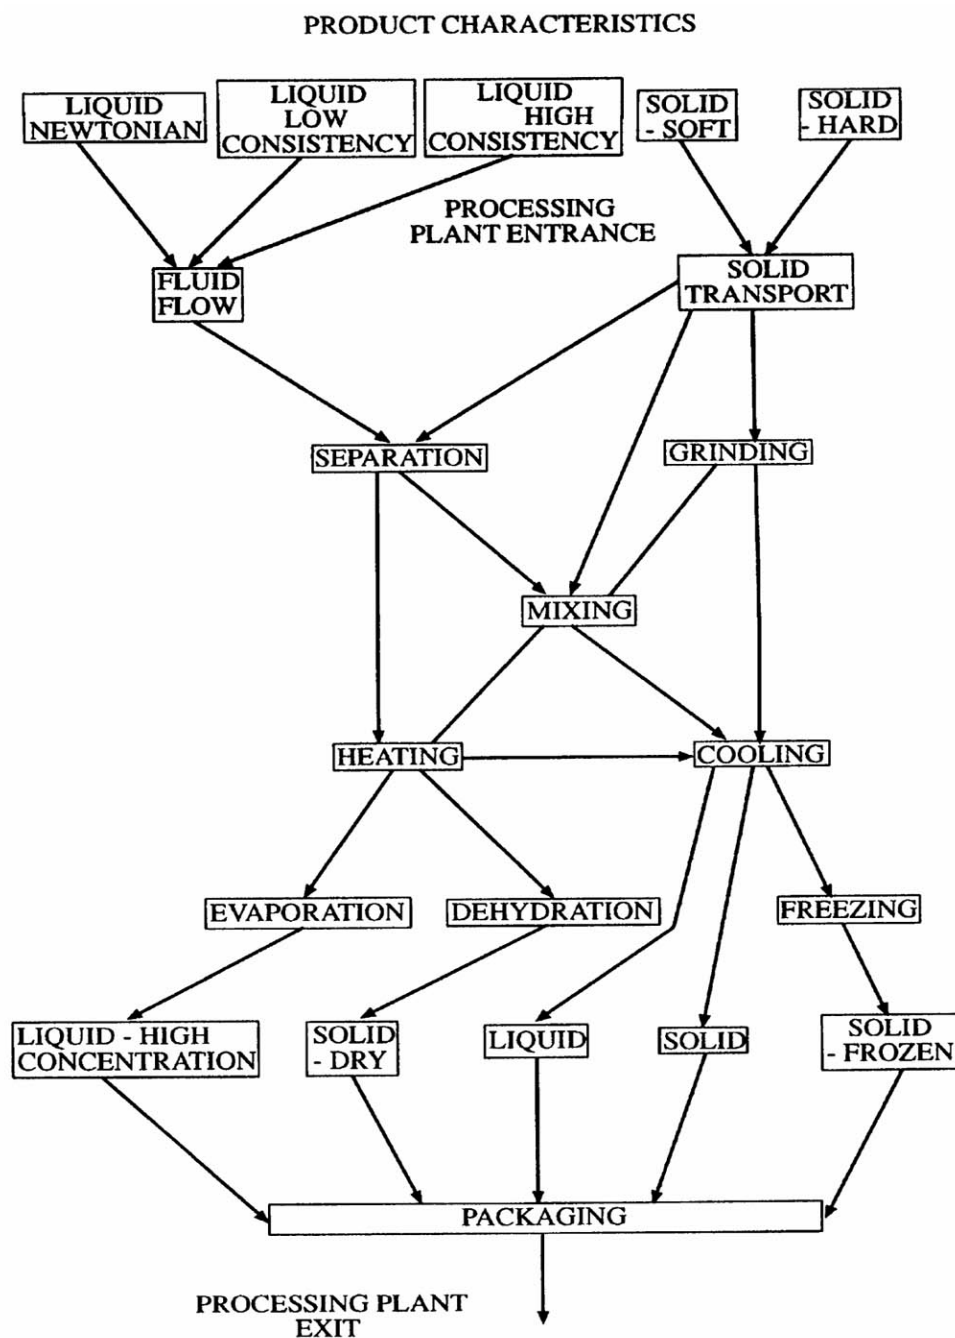

---

In a food processing plant, one of the common operations is the transport of liquid foods from one piece of processing equipment to the next. The characteristics of the liquid food must be known before a liquid transport system can be designed. As seen in [Fig. 169.2](#), a linear relationship exists between the shear stress and shear rate for a **Newtonian liquid**, such as water, orange juice, milk, and honey. The viscosity of a Newtonian liquid is determined from the slope of the straight line. Viscosity is an important property needed in many flow-related calculations. For example, viscosity of a liquid must be known before the volumetric flow rate in a pipe, under laminar conditions, can be calculated from the following equation:

$$\dot{V} = \frac{\pi \Delta P R^4}{8 \mu L} \quad (169.1)$$

**Figure 169.1** Generalized flow in a typical food manufacturing plant. (Source: Heldman, D. R. and Singh, R. P. 1981. *Food Process Engineering*, 2nd ed. AVI, Westport, CT.)

**Figure 169.2** Shear stress–shear rate relationships for Newtonian and non-Newtonian liquids. (Source: Singh, R. P. and Heldman, D. R. 1993. *Introduction to Food Engineering*, 2nd ed. Academic Press, San Diego, CA.)

For **non-Newtonian liquids**, the relationship between shear stress and shear rate is nonlinear. Non-Newtonian liquids are classified as shear thinning, shear thickening, Bingham, and plastic fluids. Both Newtonian and non-Newtonian characteristics can be described by the Herschel–Bulkley model [[Herschel and Bulkley, 1926](#)].

$$\sigma = K \left[ \frac{du}{dy} \right]^n + \sigma_0 \quad (169.2)$$

The values of the consistency coefficient,  $K$ , and the flow behavior index,  $n$ , in Eq. (169.2) are used to differentiate between different types of non-Newtonian liquids ([Table 169.1](#)). A few measured values of  $K$  and  $n$  using capillary and rotational viscometers are shown in [Table 169.2](#).

**Table 169.1** Values of Coefficients in the Herschel–Bulkley Fluid Model

Fluid	$K$	$n$	$s_0$	Typical Examples
Herschel–Bulkley	$>0$	$0 < n < 1$	$>0$	Minced fish paste, raisin paste
Newtonian	$>0$	1	0	Water, fruit juice, honey, milk, vegetable oil
Shear-thinning (pseudoplastic)	$>0$	$0 < n < 1$	0	Applesauce, banana puree, orange juice concentrate
Shear-thickening	$>0$	$1 < n < \infty$	0	Some types of honey, 40% raw corn starch solution
Bingham plastic	$>0$	1	$>0$	Toothpaste, tomato paste

Adapted from Heldman, D. R. and Singh, R.P. 1981. *Food Process Engineering*, 2nd ed. AVI, Westport, CT.

When designing transport systems for water and other Newtonian liquids, the flow regime is determined by calculating the Reynolds number. For example, a flow with Reynolds number smaller than 2100 is considered to be laminar, whereas a Reynolds number greater than 10 000 indicates turbulent flow. In the case of non-Newtonian liquid foods, a generalized Reynolds number is calculated using both the consistency coefficient  $K$  and the flow behavior index  $n$ . The generalized Reynolds number ( $N_{\text{GRe}}$ ) is defined as

$$N_{\text{GRe}} = \frac{\rho \bar{u}^{2-n} D^n}{2^{n-3} K \left[ \frac{3n+1}{n} \right]^n} \quad (169.3)$$

It is well known that for Newtonian liquids flowing in a pipe, the ratio between the mean velocity,  $\bar{u}$ , and the maximum velocity,  $u_{\text{max}}$ , under laminar conditions is given by

$$\frac{\bar{u}}{u_{\text{max}}} = 0.5 \quad (169.4)$$

Similarly, in the case of turbulent flow, for a Newtonian liquid the velocity ratio is

$$\frac{\bar{u}}{u_{\text{max}}} = 0.82 \quad (169.5)$$

In the case of non-Newtonian liquids, the velocity ratio is influenced by the flow behavior index,  $n$ , and is determined as

$$\frac{\bar{u}}{u_{\text{max}}} = \frac{n+1}{3n+1} \quad (169.6)$$

The velocity ratio for non-Newtonian liquids plotted as a function of generalized Reynolds number is shown in Fig. 169.3 [Palmer and Jones, 1976]. Knowledge of such velocity profiles is important in the design of aseptic processing systems for liquid foods.

**Figure 169.3** Plot of velocity ratio versus generalized Reynolds numbers. (Source: Palmer, J. and Jones, V. 1976. Prediction of holding times for continuous thermal processing of power law fluids. *J. Food Sci.* 41(5): 1233.)

## 169.2 Heat Transfer

Heating and cooling processes are widely used in the food industry. The three common modes of heat transfer—conduction, convection, and radiation—play an important role in the processing of foods.

The governing equation for heat transfer in the conductive mode is

$$\frac{\partial T}{\partial t} = \frac{\partial}{\partial x} \left[ \alpha \frac{\partial T}{\partial x} \right] \quad (169.7)$$

Under steady state conditions, Eq. (169.7) reduces to the well-known Fourier law:

$$q_x = -kA \frac{dT}{dx} \quad (169.8)$$

Solution of both transient and steady state equations [Eqs. (169.7) and (169.8)] requires a knowledge of the **physical and thermal properties** of foods. Considerable research has been done to measure food properties such as thermal conductivity, density, specific heat, and thermal diffusivity [Rao and Rizvi, 1995]. A computerized database developed by Singh [1993] contains over 2500 food-property combinations, along with literature citations. Some selected food property values are shown in Tables 169.3, 169.4, and 169.5. It is evident that for most high-moisture foods, the property values are greatly influenced by the presence of water. In fact, many of the empirical models used for predicting thermal properties are based on the amount of water present in a food material.

**Table 169.3** Thermal Diffusivity of Selected Foodstuffs

Product	Water Content(% wt.)	Temperature <sup>a</sup> (°C)	Thermal Diffusivity (×10 <sup>-7</sup> m <sup>2</sup> /s)

Adapted from Reidy, G. A. 1968. *Thermal Properties of Foods and Methods of Their Determination*. M.S. thesis, Michigan State University, East Lansing, MI.

Thermal conductivity of foods can be estimated from an empirical equation developed by Sweat [1995] using 430 data points.

$$k = 0.25m_c + 0.155m_p + 0.16m_f + 0.135m_a + 0.58m_m \quad (169.9)$$

A more rigorous model of thermal conductivity has been suggested by Kopelman [1966] to account for the nonisotropic nature of foods. For example, for a food material containing fibers, when the fibers in a food are parallel to the applied heat transfer, the thermal conductivity may be calculated as

$$k_{\parallel} = k_L [1 - N^2(1 - k_S/k_L)] \quad (169.10)$$

If the food fibers are perpendicular to the direction of heat transfer,

$$k_{\perp} = k_L \frac{1 - Q''}{1 - Q''(1 - N)} \quad (169.11)$$

$$Q'' = \frac{N}{(1 - k_S/k_L)} \quad (169.12)$$

Specific heat of a food material is mainly influenced by the components of the food. Thus, specific heat may be estimated from the knowledge of food composition using the following equation:

$$c_p = 1.424m_c + 1.549m_p + 1.675m_f + 0.837m_a + 4.187m_m \quad (169.13)$$

Food composition values are available in a computerized database [Singh, 1993] and *Agricultural Handbook Number 8* [Watt and Merrill, 1975]. Composition of selected foods is given in Table 169.6.

**Table 169.6** Composition of Selected Foods

Food	Water (%)	Protein (%)	Fat (%)	Carbohydrate (%)	Ash (%)
Apples, fresh	84.4	0.2	0.6	14.5	0.3
Applesauce	88.5	0.2	0.2	10.8	0.6
Asparagus	91.7	2.5	0.2	5.0	0.6
Beans, lima	67.5	8.4	0.5	22.1	1.5
Beef, hamburger, raw	68.3	20.7	10.0	0.0	1.0
Bread, white	35.8	8.7	3.2	50.4	1.9
Butter	15.5	0.6	81.0	0.4	2.5
Cod	81.2	17.6	0.3	0.0	1.2
Corn, sweet, raw	72.7	3.5	1.0	22.1	0.7
Cream, half-and-half	79.7	3.2	11.7	4.6	0.6
Eggs	73.7	12.9	11.5	0.9	1.0
Garlic	61.3	6.2	0.2	30.8	1.5
Lettuce, Iceburg	95.5	0.9	0.1	2.9	0.6
Milk, whole	87.4	3.5	3.5	4.9	0.7
Orange juice	88.3	0.7	0.2	10.4	0.4
Peaches	89.1	0.6	0.1	9.7	0.5
Peanuts, raw	5.6	26.0	47.5	18.6	2.3
Peas, raw	78.0	6.3	0.4	14.4	0.9
Pineapple, raw	85.3	0.4	0.2	13.7	0.4
Potatoes, raw	79.8	2.1	0.1	17.1	0.9
Rice, white	12.0	6.7	0.4	80.4	0.5
Spinach	90.7	3.2	0.3	4.3	1.5
Tomatoes	93.5	1.1	0.2	4.7	0.5
Turkey	64.2	20.1	14.7	0.0	1.0
Turnips	91.5	1.0	0.2	6.6	0.7
Yogurt, whole milk	88.0	3.0	3.4	4.9	0.7

Newton's law of cooling is used when the mode of heat transfer is by convection. Thus,

$$q = hA(T_p - T_\infty) \quad (169.14)$$

The convective heat transfer coefficient is determined using the lumped heat capacity method, as illustrated by Singh and Heldman [1993]. One of the key pieces of processing equipment used in the heating and cooling of foods is a heat exchanger. In the case of Newtonian liquids, both plate- and tubular-type heat exchangers are commonly used. For example, milk pasteurization is done using plate-type heat exchangers. When working with non-Newtonian liquids such as fruit purees

and pastes, or liquid foods that contain food particulates such as beef chunks in a gravy, the scraped-surface heat exchangers are used. To calculate the rate of heat transfer in Eq. (169.14) a value for the convective heat transfer coefficient must be known. For a scraped-surface heat exchanger the following relationship is recommended:

$$h = 1.2 \left( \frac{k}{D} \right) N_{\text{Re}}^{0.5} N_{\text{Pr}}^{0.33} N_m^{0.26} \quad (169.15)$$

A more complete and rigorous analysis of non-Newtonian heat transfer in scraped-surface heat exchangers is given by Harrod [1987].

Unsteady state heat transfer is important in many food processing applications. Reactions occurring in the initial stages of a heating or cooling process can significantly affect the quality attributes of foods. For example, in the food canning process, knowledge of temperature and time inside the can during the heating and cooling processes is important when designing thermal processes that ensure required microbial sterilization. Standard methods involving Heisler charts may be used to determine the temperature history of conduction heating foods [Holman, 1990]. Due to the low thermal diffusivities of foods, obtaining values of Fourier number and temperature ratios from the Heisler charts is cumbersome. Numerical methods are often employed to solve the governing heat transfer equation [Heldman and Singh, 1981].

For heating or cooling processes without phase change, the thermal diffusivity is usually a weak function of temperature. However, when a phase change occurs during a process, such as in freezing or boiling, the properties of the food material change, often dramatically. In such cases the thermal diffusivity is a strong function of temperature.

$$\alpha(T) = \frac{k(T)}{\rho(T)c_{pa}(T)} \quad (169.16)$$

Due to the nonlinearities introduced by the variable properties, more rigorous approaches are used to calculate heat transfer. In the case of freezing, food properties are influenced by the state of water. For example, a dramatic change in the specific heat of sweet cherries as a function of temperature in the freezing zone is shown in Fig. 169.4. The freezing time,  $t_F$ , may be estimated using the following equation:

$$t_F = \frac{\rho H_L}{T_F - T_\infty} \left( \frac{\text{Pa}}{h_c} + \frac{\text{Ra}^2}{k} \right) \quad (169.17)$$

**Figure 169.4** Predicted apparent specific heat of frozen sweet cherries as a function of temperature.  
(Source: Heldman, D. R. and Lund, D. B. 1992. *Handbook of Food Engineering*. Marcel Dekker, New York.)

In freezing of foods there is a phase change of water into ice. Other processes where such complexities are encountered include thawing, dehydration, and evaporation. Design considerations of such processes are elaborated in Heldman and Lund [1992] and Singh and Mannapperuma [1990].

The preceding discussion provides ample evidence that food processing offers complex situations that require the use of advanced mathematical skills to develop appropriate solutions. The data on food properties presented in this chapter show the diversity of input conditions prevalent in the design and analysis of food processing operations.

## Defining Terms

**Newtonian liquids:** Newtonian liquids exhibit a linear relationship between shear stress and rate of shear. The slope of the straight line passing through the origin of the axis is used to calculate viscosity of the liquid. Examples of Newtonian liquids include water, milk, and orange juice.

**Non-Newtonian liquids:** Non-Newtonian liquids exhibit a nonlinear relationship between shear stress and rate of shear. Furthermore, these liquids may be classified as time-independent or time-dependent non-Newtonian liquids. The rheological properties that describe non-Newtonian liquids are consistency coefficient, flow behavior index, and yield stress. Examples of non-Newtonian liquids are minced fish paste, apple sauce, banana puree, and tomato paste.

**Physical and thermal properties:** Physical and thermal properties of foods include thermal diffusivity, thermal conductivity, specific heat, density, and viscosity. A knowledge of these properties is essential in designing food processes and equipment.

## Nomenclature

Symbol	Quantity	Unit
$A$	area (normal to $x$ direction) through which heat flows	(m <sup>2</sup> )
$a$	product thickness for an infinite slab, diameter for an infinite cylinder, and diameter for a sphere	
$\alpha$	thermal diffusivity	(m <sup>2</sup> /s)
$c_{pa}$	specific heat capacity	(kJ/kg°C)
$D$	pipe diameter	(m)
$\frac{du}{dy}$	strain	s <sup>-1</sup>
$\Delta P$	pressure drop	(Pa)
$h_c$	convective heat-transfer coefficient	
$H_L$	latent heat of fusion	
$K$	consistency coefficient	(Pa·s <sup><math>n</math></sup> )
$k$	thermal conductivity	(W/m·°C)
$k_L$	thermal conductivity of liquid component	
$k_S$	thermal conductivity of solid component	
$L$	length of pipe	(m)
$\mu$	viscosity of liquid	(Pa·s)
$m_a$	mass fraction of ash	
$m_c$	mass fraction of carbohydrate	
$m_f$	mass fraction of fat	
$m_m$	mass fraction of water	
$m_p$	mass fraction of protein	
$N^2$	volume fraction of solids or discontinuous phase in the fibrous product	
$N_m$	number of blades on the mutator	
$N_{Nu}$	Nusselt number	
$N_{Pr}$	Prandtl number	
$N_{Re}$	Reynolds number	
$n$	flow behavior index	(dimensionless)
$P$	1/2, $R = 1/8$ for infinite plate; $P = 1/4$ , $R = 1/16$ for infinite cylinder $P = 1/6$ , $R = 1/24$ for sphere	

$q$	the rate of heat transfer	(W)
$q_x$	rate of heat flow in $x$ direction by conduction	(W)
$R$	radius of pipe	(m)
$\rho$	density	(kg/m <sup>3</sup> )
$\sigma$	shear stress	
$\sigma_0$	yield stress	
$T$	temperature	(°C)
$T_\infty$	surrounding temperature	(°C)
$T_F$	freezing point	(°C)
$T_p$	surface temperature	(°C)
$t$	time	(s)
$\bar{u}$	mean velocity	(m/s)
$\dot{V}$	volumetric flow rate	(m <sup>3</sup> /s)
$x$	length	(m)

## 170.1 Equipment Sizing Criteria

Field Capacity • Power Requirements

## 170.2 Equipment Selection

Soil Tillage • Crop Planting • Crop Harvest

### David J. Hills

*University of California, Davis*

Agricultural engineering is the application of engineering principles and animal/plant biology to the production, handling, processing, packaging, and use of agricultural materials. Although agricultural engineering encompasses a broad area, this chapter focuses only on crop production and specifically on equipment associated with cultural practices. The three paramount operations in crop production are soil tillage, planting, and harvesting. Additionally, judicious attention paid to water, nutriment, and plant protection can maximize crop yields.

Selection of agricultural equipment requires the consideration of three parameters that can lead to high performance: machine, power, and operation. Measures of machine performance are the rate and quality at which the operations are accomplished. Rate is an important measure because agriculture is sensitive to changeable weather and crop ripeness. Most biological materials are fragile and many are perishable, so the amount of product damage or reduction in product quality caused by a machine's operation is important. The second performance parameter that must be considered is the effectiveness with which power is applied to accomplish an agricultural operation. Selecting the proper implement for a certain task and matching the implement to the engine power are critical for obtaining high power efficiency. The final performance parameter refers to the machine operator. Knowledge of the machine's mechanisms and of the overall agricultural enterprise is needed by the operator. Sensors and automatic controls are incorporated in modern equipment for additionally improving operator efficiency.

## 170.1 Equipment Sizing Criteria

---

### Field Capacity

**Field capacity** refers to the amount of processing that a machine can accomplish per hour on either an area or a material basis. These two capacities are expressed as follows:

$$C_f = \frac{SWE}{10} \quad (170.1)$$

$$C_m = \frac{SWYE}{10} \quad (170.2)$$

where

$C_f$  = field capacity on an area basis (ha/h)  
 $C_m$  = field capacity on a material basis (t/h)  
 =  
 $S$  = travel speed (km/h)  
 $W$  = machine working width (m)  
 $Y$  = crop yield (t/ha)  
 $E$  = field efficiency (decimal)

Theoretical field capacity is used to describe a machine's capacity when the field efficiency term is equal to 1.0. This capacity implies that the machine is utilizing its full width and assumes no interruption for turns or other idle time. For cultivators and many harvesters, which work in rows, the machine working width is equal to the row spacing times the number of rows processed in each pass. Operator performance is not perfect, however, so less than the full width of such machines is used in order to ensure coverage of the entire land area; that is, there is some overlapping on each pass. A range of efficiency values for various field operations is provided in [Table 170.1](#). The actual values depend on operator skill, equipment condition, and field, crop, and environmental conditions.

**Table 170.1** Typical Field Equipment Efficiencies and Operating Speeds

Machine	Field Efficiency (%)		Speed (km/h)	
	Range	Typical	Range	Typical
Tillage				
Cultivator (field)	70–90	85	5.0–13.0	9.0
Cultivator (row crop)	70–90	80	4.0–8.0	5.5
Harrow (disk)	70–90	80	5.0–9.9	6.5
Harrow (spiketooth)	70–90	85	5.0–9.5	8.0
Harrow (springtooth)	70–90	85	5.0–9.5	8.0
Landplane	70–90	85	3.0–8.0	6.5
Plow (chisel)	70–90	85	6.5–10.5	10.5
Plow (disk)	70–90	85	3.5–9.5	7.0
Plow (moldboard)	70–90	80	5.0–9.5	7.0
Rotary hoe	70–85	80	8.0–15.5	11.0
Rotary tiller	70–90	85	1.5–7.0	5.0
Subsoiler/ripper	75–85	80	3.0–5.0	4.0
Planters

Data from *Fundamentals of Machine Operation*[Anonymous, 1976]; Kepner *et al.*[1978]; Srivastava *et al.* [1993]; and *Standards 1993*[Anonymous, 1993].

Typical operating speeds for various machines are listed in Table 170.1. Travel speeds for harvesters and other machines that process a product are limited by their materials-handling capacity. For machines that do not process a product, such as tillage machines, the speed is limited by other factors, such as available power, quality of the work, and safety.

## Power Requirements

The power required for an agricultural machine is determined by its intended use. Tractors, for example, typically provide power to implements in three forms: drawbar, rotary, and hydraulic. Pulled or towed implements are powered through the traction of drive wheels and the pull, or **draft**, from the drawbar. Rotary power is obtained from the power takeoff (PTO) shaft. Either linear or rotary power can be produced by a tractor's hydraulic system. These three power terms are defined in Eq. (170.3), (170.4), (170.5), respectively.

$$P_{db} = \frac{D_u W S}{3.6} \quad (170.3)$$

where

- $P_{db}$  = **drawbar power** (kW)
- $D_u$  = unit draft of the implement (kN)
- $W$  = machine working width (m)
- $S$  = travel speed (km/h)

$$P_{pto} = \frac{TN}{9.5} \quad (170.4)$$

where

$P_{pto}$  = **PTO power**(kW)

$T$  = torque (N-m)

$N$  = revolutions per minute (rpm)

$$P_{hyd} = \frac{pQ}{1000} \quad (170.5)$$

where

$P_{hyd}$  = hydraulic power (kW)

$p$  = pressure of pumped oil (kP)

$Q$  = oil flow rate (L/s)

Total power requirement for operating implements is the sum of implement power components converted to equivalent PTO power.

$$P_T = 1.15 \left[ \frac{P_{db}}{K_t} + P_{pto} + P_{hyd} \right] \quad (170.6)$$

where

$P_T$  = total implement power requirement (kW)

1.15 = factor that adds 15% to total power for acceleration, slope, and so on

$K_t$  = tractive and transmission efficiency (decimal)

Values for the equation variables can be obtained directly from the implement manufacturer or can be estimated from typical values as listed in [Table 170.2](#). The major factors influencing draft on tillage tools are soil characteristics, forward speed, and crop resistance. The draft for most pull-type, nontillage implements is in the form of rolling resistance.

**Table 170.2** Draft and Energy Requirements for Selected Field Equipment Operated at 5 km/h

Machine	Unit Draft (kN/m)	Energy or Work (kW-h/ha)
Tillage		
Cultivator (field)	0.9–4.4	2.4–12.0
Cultivator (row crop)	0.6–1.2	1.6–3.3
Harrow (disk)	0.7–1.5	2.0–4.0
Harrow (spiketooth)	0.3–0.9	0.7–2.4
Harrow (springtooth)	1.0–4.4	2.1–12.2
Landplane	4.4–11.7	12.2–31.3
Plow (chisel—18 to 23 cm)	2.9–13.1	8.1–36.9
Plow (moldboard or disk)		

light soils—18 cm depth	3.2–6.3	8.7–17.5
medium soils—18 cm depth	5.3–9.5	14.6–25.8
heavy soils—18 cm depth	8.5–16.6	22.1–46.1
Rotary hoe	0.4–0.9	1.3–2.4
Rotary tiller—10 cm forward slice	12.2–24.5	25.8–51.6
Subsoiler/Ripper 2 m spacing		
light soils—40 cm depth	16.0–26.3/unit	7.2–12.0
medium soils—40 cm depth	23.3–36.5/unit	10.1–15.7
Planters		
Grain drill	0.4–1.5	1.1–3.9
Row crop planter—1 m spacing	0.5–0.8/row	1.1–2.4
PTO Power (kW/m or kW/row)		
Harvesters		
Combine—small grain	3.6–11.0	7.2–22
Corn picker	1.5–3.7/row	4.4–8.8
Harvester—cotton (spindle)	7.5–11.2/row	12.9–18.4
Harvester—potato	0.7–1.5/row	8.3–13.8
Hay baler		1.2–2.0
Rotary mower (grass, legumes)	7.3–19.6	9.2–24
Miscellaneous		
Mower—flail		0.9–2.0
Sprayer—boom type	0.2 kW	0.02–0.4
Spreader—fertilizer	0.3–1.2	0.9–3.1

Data from *Fundamentals of Machine Operation*[[Anonymous, 1976](#)]; Kepner *et al.*[[1978](#)]; Srivastava *et al.* [[1993](#)]; and *Standards 1993*[[Anonymous, 1993](#)].

Approximate values for tractive and transmission efficiency for two- and four-wheel-drive tractors and crawler tractors are provided in [Table 170.3](#). As shown, tractive efficiencies for four-wheel-drive tractors are somewhat higher than those for two-wheel-drive tractors, especially for soft soils. Crawler-type tractors seldom have more than 5% slip, even on soft soils.

**Table 170.3** Tractor Tractive and Transmission Coefficients,  $K_t$

Soil Condition/Tractive Condition	Two-Wheel Drive	Four-Wheel Drive	Crawler
Concrete	0.87	0.88	—
Firm, untilled	0.72	0.78	0.82
Tilled, reasonably firm	0.67	0.75	0.80
Freshly plowed, soft	0.55	0.70	0.78

Data from Zoz [[1987](#)].

Fuel requirements for tractors can be estimated from [Table 170.4](#), provided the maximum PTO power rating and the actual PTO power requirement [as calculated by Eq. (170.6)] are known.

The drawbar power is always less than PTO power because of drive-wheel slippage, tractor rolling resistance, and friction losses in the drive between the engine and the wheels. The sum of these losses forms the basis of the tractive and transmission coefficients listed in [Table 170.3](#). These coefficients are essentially the ratios of drawbar power to PTO power.

**Table 170.4** Tractor Fuel Conversion, PTO kW-h/L

Loading, % of Maximum PTO Power	Gasoline	Diesel	LP Gas
100	1.90	2.57	1.57
80	1.74	2.50	1.49
60	1.50	2.26	1.34
40	1.16	1.87	1.09
20	0.76	1.27	0.74

Data from Kepner *et al.* [1978] and Hunt [1973].

## 170.2 Equipment Selection

### Soil Tillage

Tillage is used for seedbed preparation, weed control, incorporation of crop residues and fertilizer materials, breaking soil crusts and hardpans to improve water penetration and aeration, and shaping the soil for irrigation and erosion control. The tillage requirement is determined by the type of crop, the soil type, and the field conditions. A tillage implement consists of a single tool or a group of tools, together with the associated frame, wheels, hitch, control and protection devices, and power transmission components.

Tillage operations for seedbed preparation are often classified as primary or secondary. A primary tillage operation constitutes the initial, major soil-working operation after harvest of the previous crop. It is normally designed to reduce soil strength, cover plant materials, and rearrange soil aggregates. The main objective of secondary tillage is to break down large clods and to prepare a seedbed ideal for planting. An ideal seedbed provides for good seed-to-soil contact, conserves moisture needed for germination, and allows for vigorous and uninhibited root and shoot growth.

Implements used for primary tillage are moldboard plows, disk plows and tillers, heavy disk harrows, chisel plows, subsoilers, rotary plows, listers, and bedders. Moldboard plows and heavy disk harrows are the most commonly used primary tillage tools. Implements used for secondary tillage are disk harrows, cultivators, spike and spring tooth harrows, and rotary hoes and cultivators. The most common implement used for secondary cultivation is the disk harrow. Generally, several tillage operations are performed before the field is ready for planting. In dry climates, culti-packers are also used as the final tillage operation before planting. Increasing the soil density in the top few centimeters helps retain soil moisture.

**Example 170.1.** What is the engine power requirement for a four-wheel drive tractor pulling a three-bottom 400 mm moldboard plow to a depth of 18 cm and at a speed of 6.0 km/h on medium textured soil?

**Solution.** Data from [Tables 170.2](#) and [170.3](#) are incorporated into Eqs. (170.3) and (170.6), respectively.

$$P_{db} = \frac{(7.4)(3 \cdot 400/1000)(6)}{3.6} = 14.8 \text{ kW}$$

$$P_T = 1.15 \frac{14.8}{0.75} = 22.7 \text{ kW}$$

## Crop Planting

Agricultural plants usually begin from either seeds or seedling transplants. Important factors affecting seed germination and emergence include seed viability, soil temperature, availability of moisture and air to the seeds, and soil strength and resistance to seedling emergence. The planter can exert a strong influence on the rate of germination and emergence of seeds through control of planting depth and firming of soil around the seeds or roots of seedlings. In addition, the planter must meter seeds at the proper rate and, in some cases, must control the horizontal down-the-row placement of seeds in a desired pattern.

Equipment is available for three seeding practices: broadcasting, drilling, and precision planting. Broadcasting refers to random placement of seeds on the soil surface. Seed is metered from a hopper through a variable orifice onto a spinning disk, which accelerates the seed and distributes it. Drilling is the random down-the-row or horizontal placement of seeds in furrows that are then covered. In a seed drill, seeds are metered from a series of hoppers, typically by fluted wheels, into small furrows that are subsequently covered and pressed. High-density plantings, high costs of hand thinning, and erratic performance of mechanical thinners have resulted in the development of precision seeding techniques. In precision planting, the seeds are planted in rows at uniform spacing. Precision planters are similar in operation to press drills; however, the metering hardware is more complex, allowing for seed placement at precise depths and locations.

[Table 170.5](#) provides data on typical seeding rates and practices for selected crops. The wide ranges of seed spacing reflect the dependence on climate, season, and type of market. For agronomic crops, the lower seeding rates and wider spacings are more typical for nonirrigated conditions. For vegetable crops, spacing is determined by type of market (fresh versus processor), desired fruit size, harvesting equipment dimensions, and time of year. Depth of seeding is determined by antecedent soil moisture, soil type, and soil temperature. These data can be used to establish general criteria for planting and cultural equipment.

**Example 170.2.** A 3.4 m wide grain drill is used to plant a 50 ha field in wheat. Approximately how many hours are required for this planting operation?

**Solution.** Data from [Table 170.1](#) are used in Eq. (170.1) for determining the field capacity, and

then the operation time is calculated.

$$C_f = \frac{(6.5)(3.4)(0.7)}{10} = 1.55 \text{ ha/h}$$

$$\text{Time} = \frac{50 \text{ ha}}{1.55 \text{ ha/h}} = 32 \text{ h or four 8 h days}$$

**Table 170.5** Traditional Seed Depth and Rate for Selected Crops

Crop	Depth to Plant Seed(cm)	Spacing between Plants in Row (cm)	Spacing between Rows(cm)	No. Seeds per Gram	Seeding Rate (kg/ha)
Alfalfa	0.6–1.3	Drilled	Drilled	480	9–22
Barley	1.3–2.5	Drilled	Drilled	28	81–108
Bean, snap	2.5–3.8	10–30	46–107	4–5	75–100

## Crop Harvest

The final crop production operation is the harvesting of the plant parts that have economic value to the grower. In some cases, more than one plant part may have economic value. Many crops are highly perishable products that must be harvested within a very narrow time range, handled carefully, and either processed, properly stored, or consumed fresh soon after harvesting.

Mechanical harvesters are available for a number of crops. The general groups are hay and forage harvesters, grain harvesters, and fruit, nut, and vegetable harvesters.

Hay and forage harvesters are used in producing animal feed as ensilage or hay. Ensilage involves cutting the forage at 70 to 80% moisture, allowing it to field dry to 50 to 60% moisture, chopping it into short lengths to obtain adequate packing, and preserving it by fermentation in an airtight chamber. Equipment for the following steps are required: cut/condition, windrow, wilt, chop, transport, and store. For hay production, the forage is cut and allowed to dry to a moisture content of 15 to 23% before storage. Hay production requires equipment for the following steps: cut/condition/swath, rake into windrows, dry, bale or chop, transport, and store.

The harvesting of cereal grains, grasses, and legumes is accomplished almost entirely with the combine. A combine has five general mechanical functions: cutting, feeding, threshing, separating, and cleaning. The cutting operation is accomplished with a cutter bar and reel. The feeding mechanism distributes and delivers the crop material to the threshing cylinder in a steady uniform flow. The threshing operation is accomplished with a cylinder working against iron bar concaves. The separating mechanism extracts the straw. Cleaning of the grain, the final step, is accomplished with screening devices and blowers.

Harvesters for fruits, nuts, and vegetables are usually crop specific and may be equipped with special sensors for product selection according to maturity and size. Although these harvesters are designed for a broad range of specialty crops, they may be broadly classified according to the physical location in which the harvestable portion of the crop is located. These four crop zones are root (e.g., for sugar beets, potatoes), surface (e.g., for beans, tomatoes), bush and trellis (e.g., for boysenberries, grapes), and tree (e.g., for olives, almonds). Successful harvest mechanization requires a total systems approach, which includes varietal breeding, cultural practices, materials handling, grading and sorting, and ultimate processing. Harvester selection is therefore based on these factors, as well as such factors as economics and available labor.

**Example 170.3.** A tomato harvester is observed to travel at 4.0 km/h with a design width of 1.5 m. The average yield for the field is 80 t/ha. What is the material capacity of the machine?

**Solution.** Data from [Table 170.1](#) are used in Eq. 2 for determining the material handling capacity.

$$C_m = \frac{(4.0)(1.5)(80)(0.60)}{10} = 28.8 \text{ t/h}$$

## REAPER

*Cyrus H. McCormick Patented June 21, 1834*

Britain had seen several partially successful grain reapers invented in the 1820s. The McCormick reaper was first successfully used in the 1831 harvest on farms in his own Rockbridge County, Virginia. Cyrus's father, Robert, had built several partially successful reapers in his blacksmith shop. Father and son together built the reaper patented by Cyrus in 1834.

The traction wheel was directly behind the horse, and the grain was cut at the side, avoiding trampling. It had a vibrating cutter bar ("either smooth or with teeth"). Important, too, was a revolving reel of slats ("movable to any height required to suit the grain") to bend the grain toward the cutter and to move the cut grain to the side platform for gathering by a farmer following behind. Competition (by Hussey and others) was strong, but McCormick became very wealthy and was even elected to the French Academy in 1878 for his invention. (Courtesy of DewRay Products, Inc.)

## Defining Terms

**Draft:** The horizontal force required to propel an implement in the direction of travel.

**Drawbar power:** The power to pull or move an implement at a uniform speed. It is chiefly a function of implement draft and forward speed.

**Field capacity:** The amount of processing that a machine can accomplish per hour, expressed on either an area or a material basis.

**PTO power:** The power to operate an implement from the power-takeoff shaft. It is chiefly a function of torque and rotational speed.

Application of system reliability evaluation techniques is gaining importance because of its effectiveness in the detection, prevention, and correction of failures in the design, manufacturing, and operational phases of a product. Increasing emphasis on the reliability and quality of products and systems, coupled with pressures to minimize cost, further emphasize the need to study and quantify reliability and arrive at innovative designs.

Reliability engineering has grown significantly during the past five decades (since World War II) to encompass many subareas, such as reliability analysis, failure theory and modeling, reliability allocation and optimization, reliability growth and modeling, reliability testing (including accelerated testing), data analysis and plotting, quality control and acceptance sampling, maintenance engineering, software reliability, system safety analysis, Bayesian analysis, reliability management, simulation, Monte Carlo techniques, and economic aspects of reliability.

The objectives of this chapter are to introduce the reader to the fundamentals and applications of classical reliability concepts and bring out the importance and benefits of reliability considerations.

## 171.1 Catastrophic Failure Models

Catastrophic failure refers to the case in which repair of the component is not possible, not available, or of no value to the successful completion of the mission originally planned. Modeling such failures is typically based on life test results. We can consider the "lifetime" or "time to failure"  $T$  as a continuous random variable. Then,

$$P(\text{survival up to time } t) = P(T > t) \equiv R(t) \quad (171.1)$$

where  $R(t)$  is the *reliability* function. Obviously, as  $t \rightarrow \infty$ ,  $R(t) \rightarrow 0$  because the probability of failure increases with time of operation. Moreover,

$$P(\text{failure at } t) = P(T \leq t) \equiv Q(t) \quad (171.2)$$

where  $Q(t)$  is the unreliability function. From the definition of the distribution function of a continuous random variable, it is clear that  $Q(t)$  is indeed the distribution function for  $T$ . Therefore, the failure density function  $f(t)$  can be obtained as

$$f(t) = \frac{d}{dt}Q(t) \quad (171.3)$$

The **hazard rate function**  $\lambda(t)$  is defined as

$$\lambda(t) \equiv \lim_{\Delta t \rightarrow 0} \frac{1}{\Delta t} \left[ \text{probability of failure in } (t, t + \Delta t], \right. \\ \left. \text{given survival up to } t \right] \quad (171.4)$$

It can be shown that

$$\lambda(t) = \frac{f(t)}{R(t)} \quad (171.5)$$

The four functions  $f(t)$ ,  $Q(t)$ ,  $R(t)$ , and  $\lambda(t)$  constitute the set of functions used in basic reliability analysis. The relationships between these functions are given in [Table 171.1](#).

**Table 171.1** Relationships between Different Reliability Functions

	$f(t)$	$\lambda(t)$	$Q(t)$	$R(t)$
$f(t) =$	$f(t)$	$\lambda(t) \exp \left[ - \int_0^t \lambda(\xi) d\xi \right]$	$\frac{d}{dt}Q(t)$	$-\frac{d}{dt}R(t)$
$(t) =$	$\frac{f(t)}{1 - \int_0^t f(\xi) d\xi}$	$\lambda(t)$	$\frac{1}{1 - Q(t)} \frac{d}{dt}(Q(t))$	$-\frac{d}{dt}[\ln R(t)]$
$Q(t) =$	$\int_0^t f(\xi) d\xi$	$1 - \exp \left[ - \int_0^t \lambda(\xi) d\xi \right]$	$Q(t)$	$1 - R(t)$
$R(t) =$	$1 - \int_0^t f(\xi) d\xi$	$\exp \left[ - \int_0^t \lambda(\xi) d\xi \right]$	$1 - Q(t)$	$R(t)$

## 171.2 The Bathtub Curve

Of the four functions discussed, the hazard rate function  $\lambda(t)$  displays the different stages during the lifetime of a component most clearly. In fact, typical  $\lambda(t)$  plots have the general shape of a **bathtub curve** as shown in Fig. 171.1. The first region corresponds to *wear-in* (infant mortality) or early failures during debugging. The hazard rate goes down as debugging continues. The second region corresponds to an essentially constant and low failure rate—failures can be considered to be nearly random. This is the useful lifetime of the component. The third region corresponds to the *wear-out* or fatigue phase with a sharply increased hazard rate.

**Figure 171.1** Bathtub-shaped hazard function (Source: Ramakumar, R. 1993. *Engineering Reliability: Fundamentals and Applications*. Prentice Hall, Englewood Cliffs, NJ. With permission.)

*Burn-in* refers to the practice of subjecting components to an initial operating period of  $t_1$  (see Fig. 171.1) before delivering them to the customer. This eliminates all the initial failures from occurring after delivery to customers requiring high-reliability components. Moreover, it is prudent to replace a component as it approaches the wear-out region (i.e., after an operating period of  $(t_2 - t_1)$ ). Electronic components tend to have a long useful life (constant hazard) period. The wear-out region tends to dominate in the case of mechanical components.

## 171.3 Mean Time to Failure

The mean or expected value of the continuous random variable *time to failure* is the **mean time to failure** (MTTF). This is a very useful parameter which is often used to assess the suitability of components. It can be obtained using either the failure density function  $f(t)$  or the reliability function  $R(t)$  as follows:

$$\text{MTTF} = \int_0^{\infty} t f(t) dt \quad \text{or} \quad \int_0^{\infty} R(t) dt \quad (171.6)$$

In the case of repairable components, the repair time can also be considered as a continuous random variable with an expected value of MTTR. The mean time between failures, MTBF, is the sum of MTTF and MTTR. For well-designed components,  $\text{MTTR} \ll \text{MTTF}$ . Thus, MTBF and MTTF are often used interchangeably.

## 171.4 Average Failure Rate

---

The average failure rate over the time interval 0 to  $T$  is defined as

$$\text{AFR}(0, T) \equiv \text{AFR}(T) = -\frac{\ln R(T)}{T} \quad (171.7)$$

## 171.5 A Posteriori Failure Probability

---

When components are subjected to a burn-in (or wear-in) period of duration  $T$ , and if the component survives during  $(0, T)$ , the probability of failure during  $(T, T + t)$  is called the *a posteriori failure probability*  $Q_c(t)$ . It can be found using

$$Q_c(t) = \frac{\int_T^{T+t} f(\xi) d\xi}{\int_T^{\infty} f(\xi) d\xi} \quad (171.8)$$

The probability of survival during  $(T, T + t)$  is

$$\begin{aligned} R(t|T) &= 1 - Q_c(t) = \frac{\int_{T+t}^{\infty} f(\xi) d\xi}{\int_T^{\infty} f(\xi) d\xi} \\ &= \frac{R(T+t)}{R(T)} = \exp \left[ -\int_T^{T+t} \lambda(\xi) d\xi \right] \end{aligned} \quad (171.9)$$

## 171.6 Units for Failure Rates

---

Several units are used to express failure rates. In addition to  $\lambda(t)$ , which is usually in number per hour,  $\%/K$  is used to denote failure rates in percent per thousand hours, and  $PPM/K$  is used to express failure rate in parts per million per thousand hours. The last unit is also known as FIT for "fails in time." The relationships between these units are given in [Table 171.2](#).

**Table 171.2** Relationships between Different Failure Rate Units

	$I$ (#/hr)	%/K	PPM/K (FIT)
$\lambda =$	$I$	$10^{-5}$ (%/K)	$10^{-9}$ (PPM/K)
%/K =	$10^5 I$	%/K	$10^{-4}$ (PPM/K)
PPM/K (FIT) =	$10^9 I$	$10^4$ (%/K)	PPM/K

Source: Ramakumar, R. 1993. *Engineering Reliability: Fundamentals and Applications*. Prentice Hall, Englewood Cliffs, NJ. With permission.

## 171.7 Application of the Binomial Distribution

In an experiment consisting of  $n$  identical independent trials, with each trial resulting in success or failure with probabilities of  $p$  and  $q$ , the probability  $P_r$  of  $r$  successes and  $(n - r)$  failures is

$$P_r = {}_n C_r p^r (1 - p)^{n-r} \quad (171.10)$$

If  $X$  denotes the number of successes in  $n$  trials, then it is a discrete random variable with a mean value of  $(np)$  and variance of  $(npq)$ .

In a system consisting of a collection of  $n$  identical components with a probability  $p$  that a component is defective, the probability of finding  $r$  defects out of  $n$  is given by the  $P_r$  in Eq. (171.10). If  $p$  is the probability of success of one component and if at least  $r$  of them must be good for system success, then the system reliability (probability of system success) is given by

$$R = \sum_{k=r}^n {}_n C_k p^k (1 - p)^{n-k} \quad (171.11)$$

For systems with redundancy,  $r < n$ .

## 171.8 Application of the Poisson Distribution

For events that occur *in time* at an average rate of  $\lambda$  occurrences per unit of time, the probability  $P_x(t)$  of exactly  $x$  occurrences during the time interval  $(0, t)$  is given by

$$P_x(t) = \frac{(\lambda t)^x e^{-\lambda t}}{x!} \quad (171.12)$$

The number of occurrences  $X$  in  $(0, t)$  is a discrete random variable with a mean value of  $\mu$  of  $(\lambda t)$ , and a standard deviation  $\sigma$  of  $\sqrt{\lambda t}$ . By setting  $X = 0$  in Eq. (171.12), we obtain the probability of no occurrence in  $(0, t)$  as  $e^{-\lambda t}$ . If the event is failure, then no occurrence means success and  $e^{-\lambda t}$  is the probability of success or system reliability. This is the well-known and often used exponential distribution, also known as the constant hazard model.

## 171.9 The Exponential Distribution

---

A constant hazard rate (constant  $\lambda$ ) corresponding to the useful lifetime of components leads to the single parameter exponential distribution. The functions of interest associated with a constant  $\lambda$  are

$$f(t) = \lambda e^{-\lambda t}, t > 0 \quad (171.13)$$

$$R(t) = e^{-\lambda t} \quad (171.14)$$

$$Q(t) = Q_c(t) = 1 - e^{-\lambda t} \quad (171.15)$$

The a posteriori failure probability  $Q_c(t)$  is independent of the prior operating time  $T$ , indicating that the component does not degrade no matter how long it operates. Obviously, such a scenario is valid only during the useful lifetime (horizontal portion of the bathtub curve) of the component.

The mean and standard deviation of the random variable *lifetime* are

$$\mu \equiv \text{MTTF} = \frac{1}{\lambda} \quad \text{and} \quad \sigma = \frac{1}{\lambda} \quad (171.16)$$

## 171.10 The Weibull Distribution

---

The Weibull distribution has two parameters—a scale parameter  $\alpha$  and a shape parameter  $\beta$ . By adjusting these two parameters, a wide range of experimental data can be modeled in system reliability studies. The associated functions are

$$\lambda(t) = \frac{\beta t^{\beta-1}}{\alpha^\beta}; \quad \alpha > 0, \beta > 0, t \geq 0 \quad (171.17)$$

$$f(t) = \frac{\beta t^{\beta-1}}{\alpha^\beta} \exp \left[ - \left( \frac{t}{\alpha} \right)^\beta \right] \quad (171.18)$$

$$R(t) = \exp \left[ - \left( \frac{t}{\alpha} \right)^\beta \right] \quad (171.19)$$

With  $\beta = 1$ , the Weibull distribution reduces to the constant hazard model with  $\lambda = (1/\alpha)$ . With  $\beta = 2$ , the Weibull distribution reduces to the Rayleigh distribution.

The associated MTTF is

$$\text{MTTF} = \mu = \alpha \Gamma \left( 1 + \frac{1}{\beta} \right) \quad (171.20)$$

where  $\Gamma$  denotes the gamma function.

## 171.11 Combinatorial Aspects

Analysis of complex systems is facilitated by decomposition into functional entities consisting of subsystems or units and by the application of combinatorial considerations and network modeling techniques.

A **series structure** (or chain structure) consisting of  $n$  units is shown in Fig. 171.2. From the reliability point of view, the system will succeed only if all the units succeed. The units may or may not be physically in series. If  $R_i$  is the probability of success of the  $i$ th unit, then the series system reliability  $R_s$  is given as

$$R_s = \prod_{i=1}^n R_i \quad (171.21)$$

if the units do not interact with each other. If they do, then the conditional probabilities must be carefully evaluated.

**Figure 171.2** Series or chain structure. (Source: Ramakumar, R. 1993. *Engineering Reliability: Fundamentals and Applications*. Prentice Hall, Englewood Cliffs, NJ. With permission.)

If each of the units has a constant hazard, then

$$R_s(t) = \prod_{i=1}^n \exp(-\lambda_i t) \quad (171.22)$$

where  $\lambda_i$  is the constant failure rate for the  $i$ th unit or component. This enables us to replace the  $n$  components in series by an equivalent component with a constant hazard  $\lambda_s$  where

$$\lambda_s = \sum_{i=1}^n \lambda_i \quad (171.23)$$

If the components are identical, then  $\lambda_s = n\lambda$  and the MTTF for the equivalent component is  $(1/n)$  of the MTTF of one component.

A **parallel structure** consisting of  $n$  units is shown in Fig. 171.3. From the reliability point of view, the system will succeed if any one of the  $n$  units succeeds. Once again, the units may or may

not be physically or topologically in parallel. If  $Q_i$  is the probability of failure of the  $i$ th unit, then the parallel system reliability  $R_p$  is given as

$$R_p = 1 - \prod_{i=1}^n Q_i \quad (171.24)$$

if the units do not interact with each other (i.e., are independent).

**Figure 171.3** Parallel structure. (Source: Ramakumar, R. 1993. *Engineering Reliability: Fundamentals and Applications*. Prentice Hall, Englewood Cliffs, NJ. With permission.)

If each of the units has a constant hazard, then

$$R_p(t) = 1 - \prod_{i=1}^n [1 - \exp(-\lambda_i t)] \quad (171.25)$$

and we do not have the luxury of being able to replace the parallel system by an equivalent component with a constant hazard. The parallel system does not exhibit constant hazard even though each of the units has constant hazard.

The MTTF of the parallel system can be obtained by using Eq. (171.25) in Eq. (171.6). The results for the case of components with identical hazards  $\lambda$  are:  $(1.5/\lambda)$ ,  $(1.833/\lambda)$ , and  $(2.083/\lambda)$  for  $n = 2, 3$ , and  $4$ , respectively. The largest gain in MTTF is obtained by going from one component to two components in parallel. It is uncommon to have more than two or three components in a truly parallel configuration because of the cost involved. For two nonidentical components in parallel with hazard rates  $\lambda_1$  and  $\lambda_2$ , the MTTF is given as

$$\text{MTTF} = \frac{1}{\lambda_1} + \frac{1}{\lambda_2} - \frac{1}{\lambda_1 + \lambda_2} \quad (171.26)$$

An  $r$ -out-of- $n$  structure, also known as a partially redundant system, can be evaluated using Eq. (171.11). If all the components are identical, independent, and have a constant hazard  $\lambda$ , then the system reliability can be expressed as

$$R(t) = \sum_{k=r}^n {}_n C_k e^{-k\lambda t} (1 - e^{-\lambda t})^{n-k} \quad (171.27)$$

For  $r = 1$ , the structure becomes a parallel system. For  $r = n$ , it becomes a series system.

Series-parallel systems are evaluated by repeated application of the expressions derived for series and parallel configurations by employing the well-known network reduction techniques.

Several general techniques are available for evaluating the reliability of complex structures that do not come under purely series or parallel or series-parallel. They range from inspection to cutset and tieset methods and connection matrix techniques that are amenable to computer programming.

## 171.12 Modeling Maintenance

---

Maintenance of a component could be a scheduled (preventative) one or a forced (corrective) one. The latter follows in-service failures and can be handled using Markov models discussed later. Scheduled maintenance is conducted at fixed intervals of time, irrespective of the system continuing to operate satisfactorily.

Scheduled maintenance, under ideal conditions, takes very little time (compared to the time between maintenances) and the component is restored to an "as new" condition. Even if the component is irreparable, scheduled maintenance postpones failure and prolongs the life of the component. Scheduled maintenance makes sense only for those components with increasing

hazard rates. Most mechanical systems come under this category. It can be shown that the density function  $f_T^*(t)$ , with scheduled maintenance included, can be expressed as

$$f_T^*(t) = \sum_{k=0}^{\infty} f_1(t - kT_M) R^k(T_M) \quad (171.28)$$

where

$$f_1(t) = \begin{cases} f_T(t) & \text{for } 0 < t \leq T_M \\ 0 & \text{otherwise} \end{cases} \quad (171.29)$$

and

$R(t)$  = component reliability function  
 $T_M$  = time between maintenance, constant  
 $f_T(t)$  = original failure density function

In Eq. (171.28),  $k = 0$  is used only between  $t = 0$  and  $t = T_M$ , and  $k = 1$  is used only between  $t = T_M$  and  $t = 2T_M$  and so on.

A typical  $f_T^*(t)$  is shown in Fig. 171.4. The time scale is divided into equal intervals of  $T_M$  each. The function in each segment is a scaled-down version of the one in the previous segment, the scaling factor being equal to  $R(T_M)$ . Irrespective of the nature of the original failure density function, scheduled maintenance gives it an exponential tendency. This is another justification for the widespread use of exponential distribution in system reliability evaluations.

**Figure 171.4** Density function with ideal scheduled maintenance incorporated. (Source: Ramakumar, R. 1993. *Engineering Reliability: Fundamentals and Applications*. Prentice Hall, Englewood Cliffs, NJ. With permission.)

## 171.13 Markov Models

---

Of the different Markov models available, the discrete-state, continuous-time Markov process has found many applications in system reliability evaluation, including the modeling of repairable systems. The model consists of a set of discrete states (called the state space) in which the system can reside and a set of transition rates between appropriate states. Using these, a set of first-order differential equations is derived in the standard vector-matrix form for the time-dependent probabilities of the various states. Solution of these equations incorporating proper initial conditions gives the probabilities of the system residing in different states as functions of time. Several useful results can be gleaned from these functions.

## 171.14 Binary Model for a Repairable Component

---

The binary model for a repairable component assumes that the component can exist in one of two states—the *up* state or the *down* state. The transition rates between these two states,  $S_0$  and  $S_1$ , are assumed to be constant and equal to  $\lambda$  and  $\mu$ . These transition rates are the constant failure and repair rates implied in the modeling process and their reciprocals are the MTTF and MTTR, respectively. Figure 171.5 illustrates the binary model.

**Figure 171.5** State space diagram for a single repairable component. (Source: Ramakumar, R. 1993. *Engineering Reliability: Fundamentals and Applications*. Prentice Hall, Englewood Cliffs, NJ. With permission.)

The associated Markov differential equations are

$$\begin{bmatrix} P_0'(t) \\ P_1'(t) \end{bmatrix} = \begin{bmatrix} -\lambda & \mu \\ \lambda & -\mu \end{bmatrix} \begin{bmatrix} P_0(t) \\ P_1(t) \end{bmatrix} \quad (171.30)$$

with the initial conditions

$$\begin{bmatrix} P_0(0) \\ P_1(0) \end{bmatrix} = \begin{bmatrix} 1 \\ 0 \end{bmatrix} \quad (171.31)$$

The coefficient matrix of Markov differential equations, namely

$$\begin{bmatrix} -\lambda & \mu \\ \lambda & -\mu \end{bmatrix},$$

is obtained by transposing the matrix of rates of departures

$$\begin{bmatrix} 0 & \lambda \\ \mu & 0 \end{bmatrix}$$

and replacing the diagonal entries by the negative of the sum of all the other entries in their respective columns. Solution of Eq. (171.30) with initial conditions as given by Eq. (171.31) yields

$$P_0(t) = \frac{\mu}{\lambda + \mu} + \frac{\lambda}{\lambda + \mu} e^{-(\lambda + \mu)t} \quad (171.32)$$

$$P_1(t) = \frac{\lambda}{\lambda + \mu} \left[ 1 - e^{-(\lambda + \mu)t} \right] \quad (171.33)$$

The limiting, or steady state, probabilities are found by letting  $t \rightarrow \infty$ . They are also known as limiting **availability**  $A$  and limiting unavailability  $U$  and they are

$$P_0 = \frac{\mu}{\lambda + \mu} \equiv A \quad \text{and} \quad P_1 = \frac{\lambda}{\lambda + \mu} \equiv U \quad (171.34)$$

The time-dependent  $A(t)$  and  $U(t)$  are simply  $P_0(t)$  and  $P_1(t)$ , respectively.

Referring back to Eq. (171.14) for a constant hazard component and comparing it with Eq. (171.32) which incorporates repair, the difference between  $R(t)$  and  $A(t)$  becomes obvious. Availability  $A(t)$  is the probability that the component is up at time  $t$ , and reliability  $R(t)$  is the probability that the system has continuously operated from 0 to  $t$ . Thus,  $R(t)$  is much more stringent than  $A(t)$ . While both  $R(0)$  and  $A(0)$  are unity,  $R(t)$  drops off rapidly as compared to  $A(t)$  as time progresses. With a small value of MTTR (or large value of  $\mu$ ), it is possible to realize a very high availability for a repairable component.

## 171.15 Two Dissimilar Repairable Components

Irrespective of whether the two components are in series or in parallel, the state space consists of four possible states:  $S_1$  (1 up, 2 up),  $S_2$  (1 down, 2 up),  $S_3$  (1 up, 2 down), and  $S_4$  (1 down, 2 down). The actual system configuration will determine which of these four states correspond to system success and failure. The associated state space diagram is shown in Fig. 171.6. Analysis of this system results in the following steady state probabilities:

$$P_1 = \frac{\mu_1 \mu_2}{\text{Denom}}; \quad P_2 = \frac{\lambda_1 \mu_2}{\text{Denom}}; \quad P_3 = \frac{\lambda_2 \mu_1}{\text{Denom}}; \quad P_4 = \frac{\lambda_1 \lambda_2}{\text{Denom}} \quad (171.35)$$

where

$$\text{Denom} \equiv (\lambda_1 + \mu_1)(\lambda_2 + \mu_2) \quad (171.36)$$

For components in series,  $A = P_1$ ,  $U = (P_2 + P_3 + P_4)$ , and the two components can be replaced by an equivalent component with a failure rate of  $\lambda_s = (\lambda_1 + \lambda_2)$  and a mean repair duration of  $r_s$ , where

$$r_s \cong \frac{\lambda_1 r_1 + \lambda_2 r_2}{\lambda_s} \quad (171.37)$$

Extending this to  $n$  components in series, the equivalent system will have

$$\lambda_s = \sum_{i=1}^n \lambda_i \quad \text{and} \quad r_s \cong \frac{1}{\lambda_s} \sum_{i=1}^n \lambda_i r_i \quad (171.38)$$

$$\text{and system unavailability} = U_s \cong \lambda_s r_s = \sum_{i=1}^n \lambda_i r_i \quad (171.39)$$

For components in parallel,  $A = (P_1 + P_2 + P_3)$ ,  $U = P_4$ , and the two components can be replaced by an equivalent component with

$$\lambda_p \cong \lambda_1(\lambda_2 r_1) + \lambda_2(\lambda_1 r_2) \quad \text{and} \quad \mu_p = \mu_1 + \mu_2 \quad (171.40)$$

$$\text{and system unavailability} = U_p = \lambda_p(1/\mu_p) \quad (171.41)$$

Extension to more than two components in parallel follows similar lines. For three components in parallel,

$$\mu_p = (\mu_1 + \mu_2 + \mu_3) \quad \text{and} \quad U_p = \lambda_1 \lambda_2 \lambda_3 r_1 r_2 r_3 \quad (171.42)$$

**Figure 171.6** State space diagram for two dissimilar reparable components. (Source: Ramakumar, R. 1993. *Engineering Reliability: Fundamentals and Applications*. Prentice Hall, Englewood Cliffs, NJ. With permission.)

### 171.16 Two Identical Reparable Components

In this case, only three states are needed to complete the state space:  $S_1$  (both up),  $S_2$  (one up and one down), and  $S_3$  (both down). The corresponding state space diagram is shown in Fig. 171.7. Analysis of this system results in the following steady state probabilities:

$$P_1 = \left( \frac{\mu}{\lambda + \mu} \right)^2 ; \quad P_2 = \frac{2\lambda}{\mu} \left( \frac{\mu}{\lambda + \mu} \right)^2 ; \quad P_3 = \left( \frac{\lambda}{\lambda + \mu} \right)^2 \quad (171.43)$$

**Figure 171.7** State space diagram for two identical reparable components. (Source: Ramakumar, R. 1993. *Engineering Reliability: Fundamentals and Applications*. Prentice Hall, Englewood Cliffs, NJ. With permission.)

## 171.17 Frequency and Duration Techniques

---

The expected residence time in a state is the mean value of the passage time from the state in question to any other state. Cycle time is the time required to complete an *in* and *not in* cycle for that state. Frequency of occurrence (or encounter) for a state is the reciprocal of its cycle time. It can be shown that the frequency of occurrence of a state is equal to the steady state probability of being in that state multiplied by the total rate of departure from it. Also, the expected value of the residence time is equal to the reciprocal of the total rate of departure from that state.

Under steady state conditions, the expected frequency of entering a state must be equal to the expected frequency of leaving that state (this assumes that the system is *ergodic*, which will not be elaborated for lack of space). Using this principle, frequency balance equations can be easily written (one for each state) and solved in conjunction with the fact that the sum of the steady state probabilities of all the states must be equal to unity to obtain the steady state probabilities. This procedure is much simpler than solving the Markov differential equations and letting  $t \rightarrow \infty$ .

## 171.18 Applications of Markov Process

---

Once the different states are identified and a state space diagram is developed, Markov analysis can proceed systematically (probably with the help of a computer in the case of large systems) to yield a wealth of results used in system reliability evaluation. Inclusion of installation time after repair, maintenance, spare, and stand-by systems, and limitations imposed by restricted repair facilities are some of the many problems that can be studied.

## 171.19 Some Useful Approximations

---

For an  $r$ -out-of- $n$  structure with failure and repair rates of  $\lambda$  and  $\mu$  for each, the equivalent MTTR and MTTF can be approximated as

$$\text{MTTR}_{\text{eq}} = \frac{\text{MTTR of one component}}{n - r + 1} \quad (171.44)$$

$$\text{MTTF}_{\text{eq}} = \left( \begin{matrix} \text{MTTF} \\ \text{of one component} \end{matrix} \right) \left( \frac{\text{MTTF}}{\text{MTTR}} \right)^{n-r} \left[ \frac{(n-r)!(r-1)!}{n!} \right] \quad (171.45)$$

The influence of weather must be considered for components operating in an outdoor environment. If  $\lambda$  and  $\lambda'$  are the normal weather and stormy weather failure rates,  $\lambda'$  will be much greater than  $\lambda$ , and the average failure rate  $\lambda_f$  can be approximated as

$$\lambda_f \cong \left( \frac{N}{N+S} \right) \lambda + \left( \frac{S}{N+S} \right) \lambda' \quad (171.46)$$

where  $N$  and  $S$  are the expected durations of normal and stormy weather. For well-designed, high-reliability components, the failure rate  $\lambda$  will be very small and  $\lambda t \ll 1$ . Then, for a single component,

$$R(t) \cong 1 - \lambda t \quad \text{and} \quad Q(t) \cong \lambda t \quad (171.47)$$

and for  $n$  dissimilar components in series,

$$R(t) \cong 1 - \sum_{i=1}^n \lambda_i t \quad \text{and} \quad Q(t) \cong \sum_{i=1}^n \lambda_i t \quad (171.48)$$

For the case of  $n$  identical components in parallel,

$$R(t) \cong 1 - (\lambda t)^n \quad \text{and} \quad Q(t) \cong (\lambda t)^n \quad (171.49)$$

For the case of an  $r$ -out-of- $n$  configuration,

$$Q(t) \cong {}_nC_{n-r+1} (\lambda t)^{n-r+1} \quad (171.50)$$

Equations (171.47)–(171.50) are called rare-event approximations.

## Defining Terms

**Availability:** The availability  $A(t)$  is the probability that a system is performing its required function successfully at time  $t$ . The steady state availability  $A$  is the fraction of time that an item, system, or component is able to perform its specified or required function.

**Bathtub curve:** For most physical components and living entities, the plot of failure (or hazard) rate versus time has the shape of the longitudinal cross section of a bathtub.

**Hazard rate function:** The plot of instantaneous failure rate versus time is called the hazard function. It clearly and distinctly exhibits the different life cycles of the component.

**Mean time to failure:** The mean time to failure (MTTF) is the mean or expected value of time to failure.

**Parallel structure:** Also known as a completely redundant system, it describes a system that can succeed when at least one of two or more components succeeds.

**Redundancy:** Refers to the existence of more than one means, identical or otherwise, for accomplishing a task or mission.

**Reliability:** The reliability  $R(t)$  of an item or system is the probability that it has performed successfully over the time interval from 0 to  $t$ . In the case of irreparable systems,  $R(t) = A(t)$ . With repair,  $R(t) \leq A(t)$ .

**Series structure:** Also known as a chain structure or nonredundant system, it describes a system whose success depends on the success of all of its components.

AERONAUTICAL AND AEROSPACE ENGINEERING offers extraordinary challenges. Aircraft and spacecraft missions can range from medical evacuation to air superiority to robotic exploration of distant planets. Flight distances can be semi-infinite—launched from earth but never returning—and speeds can range from zero to over 50,000 km/h. And all of this has to be accomplished with aircraft or spacecraft that ideally should have no weight and require no fuel.

Aerodynamics, a subdiscipline of fluid dynamics, is a concern for any object that moves through an atmosphere. For aircraft, it is the principal concern. **Chapter 172** lays the groundwork for understanding aerodynamics, beginning with Bernoulli's equation and continuing to more complex topics, such as supersonic flight.

Traditional aerodynamics has relied on wind tunnel testing to confirm analytical results; however, in recent times the emergence of computational fluid dynamics (CFD) has sharply reduced the need for such testing. CFD is a computationally demanding task that requires

supercomputers, but the speed and accuracy with which candidate aerodynamic configurations can be analyzed often makes CFD the preferred approach. **Chapter 174** examines the "mathematical wind tunnel."

No one has ever built a weightless aircraft or spacecraft. However, modern materials—specifically, advanced composites—have enabled ever lighter vehicles to accomplish the same or more demanding missions than their predecessors. As the capabilities of advanced materials have grown, their use in aircraft and spacecraft has more than kept pace. The broad spectrum of advanced materials properties, combined with the equally broad spectrum of aircraft and spacecraft missions and operating environments, dictates careful selection of materials.

**Chapter 175** reviews advanced materials for aerospace applications and describes a proven procedure developed by the Boeing Commercial Airplane Co. to ensure selection of the correct one.

Regardless of the mission, every aircraft and spacecraft must have mobility—mobility derived from propulsion. The fundamentals of propulsion, with emphasis on rocket examples, are found in **Chapter 176**.

The design of aircraft and spacecraft begins with a clear statement and understanding of the mission requirements; otherwise the result will be the wrong product performing the wrong functions. Because of the wide speed range and diversity of operating environments, noted in the first paragraph, aircraft design is a series of compromises, typically trading off maneuverability for weight or safety. For spacecraft, particularly unmanned ones, weight, operational flexibility, and reliability are the principal design factors. **Chapters 177** and **178** capture the salient points of the design process for their respective vehicles.

*Aerodynamics* is a subset of fluid dynamics that deals with the flow of air about objects, typically aircraft, missiles, or their components. Much of the work in aerodynamics focuses on the generation of forces and moments on a body due to the air flowing over and through the body. Aerodynamics deals with theoretical and numerical predictions of performance characteristics, experimental determination of performance characteristics, and the design of new and improved geometries using this information. This chapter provides the basic understanding and equations to enable the engineer to calculate the performance of many aerodynamic configurations and interpret aerodynamic data.

## 172.1 Background

---

Understanding aerodynamics requires a knowledge of the basic principles of fluid mechanics. These principles are covered in Section VI. However, several key points required for the understanding of aerodynamics are provided in this section.

To understand how lift is generated, it is important to know the relationship between velocity and pressure in a fluid flow. For flows where the effects of viscosity are negligible, the density is constant, and gravity does not play a role, *Bernoulli's equation* describes this relationship:

$$p + \rho \frac{V^2}{2} = p_0 = \text{constant along a streamline} \quad (172.1)$$

where  $p$  is the static pressure,  $\rho$  is the density of the fluid medium, and  $V$  is the fluid velocity. The constant in Eq. (172.1) is the total pressure, denoted  $p_0$ , and is the sum of the static pressure,  $p$ , and the dynamic pressure,  $\rho V^2/2$ . A *streamline* is the path a fluid particle makes in the flow assuming the flow is steady, and Eq. (172.1) indicates that the total pressure is constant along this line. If the

velocity and pressure are known at one point on the streamline, the flow quantities can be computed at another point on the streamline by rewriting Eq. (172.1) as

$$p_2 + \rho \frac{V_2^2}{2} = p_1 + \rho \frac{V_1^2}{2} \quad (172.2)$$

where the subscripts refer to two points along the streamline. The total pressure is a measure of the energy in the flow and Eq. (172.1) indicates that this energy is shared between the static pressure and the dynamic pressure (kinetic energy). If the velocity goes to zero at a point in the flowfield, this point is referred to as a *stagnation point* and the pressure there is the stagnation pressure, which is equal to the total pressure.

The effects of *viscosity* and the *no-slip* condition are also important concepts for the understanding of aerodynamics. When a fluid moves over the surface of a body, it actually "sticks" to the surface of the body so that there is no relative velocity between the fluid and the surface. This is called the no-slip condition and is caused by intermolecular forces and molecular-scale surface roughness. Due to the effects of viscosity, a *boundary layer* is formed near the surface where the velocity increases from zero at the surface to the freestream value,  $U_\infty$ , far away (see Fig. 172.1). Viscous effects are important only in the boundary layer for most streamlined bodies. Since viscous effects are important in the boundary layer, Bernoulli's equation cannot be applied there. In fact, in the absence of strong curvature, the pressure at the wall where the velocity is zero is equal to the static pressure in the outer flow and not the total pressure as predicted by Bernoulli's equation.

**Figure 172.1** Velocity profile in a boundary layer.

*Reynolds number* is a measure of the importance of viscous effects and is defined as the ratio of

momentum forces to viscous forces:

$$\text{Re} = \frac{U_{\infty} \rho l}{\mu} \quad (172.3)$$

where  $l$  is a length scale of the flowfield and  $\mu$  is the viscosity of the fluid. As the Reynolds number is increased, the effects of viscosity become less important.

## 172.2 Flow about a Body

---

This section describes the forces developed in a constant-density flow about general bodies. [Figure 172.2](#) illustrates the flow about an arbitrary two-dimensional body. The body is traveling through still air at a velocity of  $U_{\infty}$  and the figure is drawn in the reference frame of the body so the fluid appears to move past the body. Two forces are generated—**lift**,  $L$ , and **drag**,  $D$ . Lift is the force perpendicular to the incoming velocity and drag is the force parallel to the incoming velocity. A *moment*,  $M$ , is also exerted on the body. As the freestream velocity changes, the forces on the body change even if the flowfield remains approximately similar. It is therefore useful to define nondimensional force coefficients which vary much less with flow speed than the forces themselves. The forces are nondimensionalized by the dynamic pressure times an area associated with the body,  $S$  (in the case of a wing, it is usually the wing area). The lift and drag coefficients are defined as

$$C_L \equiv \frac{L}{\frac{1}{2} \rho U_{\infty}^2 S} \quad (172.4)$$

$$C_D \equiv \frac{D}{\frac{1}{2} \rho U_{\infty}^2 S} \quad (172.5)$$

The moment coefficient is defined using an additional parameter,  $l$ , a length scale of the body (in the case of a wing, it is usually the streamwise length of the wing), as

$$C_M \equiv \frac{M}{\frac{1}{2} \rho U_{\infty}^2 S l} \quad (172.6)$$

The particular choice of the reference area and length is not critical, but when using published data it is important to know which reference quantities the coefficients are based upon.

**Figure 172.2** Flow about an arbitrary two-dimensional body illustrating the aerodynamic forces and moment exerted by the flowfield. The reference frame is fixed to the body.

Two types of forces act on the surface of a body due to the motion of the fluid—*pressure forces* and *viscous forces*. Pressure forces are simply due to the pressure,  $p$ , and act perpendicular to the surface. Viscous forces, or friction forces, are caused by the flow "rubbing" against the surface as it passes over the body. This force acting on a unit area of the surface is termed the *wall shear stress*,  $\tau_w$ , and acts tangentially to the surface. It is proportional to the velocity gradient normal to the wall at the wall, and is defined as

$$\tau_w = \mu \left. \frac{\partial U}{\partial y} \right|_w \quad (172.7)$$

where  $\mu$  is the viscosity and the subscript  $w$  denotes that the derivative is evaluated at the wall. No matter how complex the surface geometry or the flowfield, the only way aerodynamic forces are transmitted to a body is through these two mechanisms.

## Lift

A lift force is generated on a body by pressure differences between the top and bottom of the body. If the average pressure over the bottom of the body is higher than the average pressure over the top of the body, the lift force points upward. If we consider the flow over a two-dimensional cylinder without viscosity, the streamline pattern is symmetric, as shown in Fig. 172.3(a). The presence of the cylinder in the flow requires the same amount of fluid to pass in a smaller area. Thus, the fluid must speed up in some regions of the flowfield. A fluid element moving along the centerline slows down to zero velocity at the stagnation point  $A$ , where the pressure is equal to the total pressure. As the fluid moves away from the center of the cylinder, it speeds up, and a minimum pressure occurs in the two regions marked  $B$ . This reduction in pressure can be seen using Bernoulli's equation [Eq. (172.1)] because, as the flow speeds up, the static pressure drops in order for the total pressure to remain constant. The fluid slows down again towards the rear of the cylinder as the streamlines come together and another stagnation point is formed at  $C$ . The total lift force is the integral of the pressure over the entire surface in a direction perpendicular to the freestream flow:

$$L = \int p dA_y \quad (172.8)$$

where  $A_y$  is the component of the area perpendicular to the freestream flow. Thus, on the upper surface of the cylinder, there is an upward force, but there is an equal and opposite downward force on the lower surface because the flow is symmetric, and the net lift is zero.

**Figure 172.3** Flow about a cylinder without spin (a) and with spin (b).

If the cylinder is spun about its axis, as shown in Fig. 172.3(b), the flow pattern becomes asymmetric. The stagnation points at A and C have moved below the centerline and the minimum pressure occurs only on the upper surface. In this case, it can be seen that the average pressure over the lower half of the cylinder will be higher than that over the top because the stagnation points are both on the bottom. In this case, there is a net lift force pointing up. The same effect is used in the aerodynamics of sport balls. For example, in tennis, a top spin on the ball causes it to drop much more quickly than a ball without top spin because of the downward-pointing lift vector.

By spinning the cylinder, a *circulation* has been introduced about the body. Circulation,  $\Gamma$ , is related to the average velocity tending to move fluid elements around the body. This average is made up of velocities on a path encircling the body. However, a nonzero value of circulation does not indicate that the fluid elements are actually moving around the cylinder. As the cylinder is spun faster, and  $\Gamma$  is thus increased, the lift force increases.

The relationship between lift and circulation is termed the *Kutta-Joukowski theorem* after the two people who independently discovered it, and is expressed as

$$L' = \rho U_\infty \Gamma \quad (172.9)$$

where  $L'$  is the lift per unit span of the cylinder. This theorem applies to any two-dimensional body

about which a circulation exists, not just a cylinder. Circulation about a body can be represented as a **vortex**. A vortex is a circular flowfield in which the fluid rotates about a common axis, and the farther the fluid element is from the axis, the slower it moves around the axis. In the case of lift generation, the vortex is not attached to the same fluid elements, but is "bound" to the body and is often called a *bound vortex*.

## Drag

For a general body, the total drag force results from two sources—*pressure drag* and *viscous drag*. Pressure drag is simply the component of the total pressure force on the body that is in the streamwise direction (parallel to the direction of the freestream). In many flows, *boundary layer separation* causes significant pressure drag. Boundary layer separation can occur when a boundary layer flows into a region of increasing pressure. For fluid elements outside the boundary layer, this increase in pressure is traded off as a decrease in velocity, as can be seen by Bernoulli's equation. Because the pressure is approximately constant across the boundary layer, the fluid near the wall must also undergo an increase in pressure. The fluid near the wall has less energy than the flow at the edge of the boundary layer because it is moving slower. If the pressure increases too rapidly in the downstream direction, the velocity near the wall can reverse. If this happens, the boundary layer is said to have separated, as shown in Fig. 172.4. The boundary layer leaves the surface and a recirculating region is developed between the airfoil surface and the boundary layer fluid that left the surface. As the flow is not attached to the surface, it does not continue on a path which leads to a higher pressure in that region as it would if the flow had not separated. The result is a lower pressure acting over the surface. This surface usually has a component of area facing downstream and the low pressure acting on this area is seen as drag (pressure drag). Pressure drag,  $D_p$ , is calculated as

$$D_p = \int p dA_x \quad (172.10)$$

where  $A_x$  is the streamwise component of the area. For this reason, boundary layer separation is usually considered to have a negative effect on a flow.

**Figure 172.4** Diagram illustrating boundary layer separation.

Viscous drag,  $D_v$ , is present in all vehicles which move through a fluid. It is caused by the wall shear stress, which was discussed earlier in this section. Wall shear stress acts tangentially to the surface, so the total viscous drag is determined by integrating the streamwise component of  $\tau_w$  over the surface:

$$D_v = \int \tau_w dA_x \quad (172.11)$$

### 172.3 Two-Dimensional Airfoils

Typically, wings have been analyzed by splitting the problem into two parts: (1) analysis of a wing section (*airfoil*), and (2) modification of the airfoil properties to account for the effects of the complete, finite wing. An airfoil is the cross section of a wing in a plane parallel to the freestream velocity and perpendicular to the wing, as shown in Fig. 172.5.

**Figure 172.5** Diagram illustrating the relationship between an aircraft wing and an airfoil.

Airfoils are usually described using the nomenclature indicated in Fig. 172.6. The longest dimension of the airfoil section is termed the *chord*, and the line connecting the *leading edge* to the *trailing edge* is the *chord line*. Airfoil *thickness* is the maximum distance between the upper and lower surfaces along a line perpendicular to the chord line. Thickness is usually expressed as a percentage of the chord (e.g., a 12% thick airfoil has a maximum thickness of 12% of the chord). The *mean camber line* is the locus of points halfway between the upper and lower surfaces. The variation of the thickness along the mean camber line is termed the *thickness distribution*. *Camber* of the airfoil is defined as the maximum distance between the mean camber line and the chord line in a direction perpendicular to the chord line. When a fluid is moving past the airfoil, the angle of attack is defined as the angle between the freestream velocity and the chord line, denoted as  $\alpha$  in Fig. 172.6.

**Figure 172.6** Airfoil terminology.

Airfoil designs that cover a wide range of thickness, thickness distributions, and camber have been designed and tested by the National Advisory Committee for Aeronautics (NACA) (the predecessor of the current NASA). These include the *four-digit* series (e.g., the NACA 2412), the *five-digit* series (e.g., the NACA 23012), and the *six-digit* series (e.g., the NACA 65-218). The numbers indicate different characteristics of the airfoils. A complete description of the numbering system can be found in Abbott and von Doenhoff [1959]. These and other airfoil designs and their performance characteristics can be found in the books in the Further Information section.

In selecting an airfoil for a particular application, the variation of lift, drag, and moment with angle of attack is necessary. A typical variation of lift coefficient with angle of attack is shown in Fig. 172.7. Recall from the earlier discussion that this data represents the performance of a two-dimensional airfoil and is sometimes referred to as *infinite wing data*. The value of  $\alpha$  when the lift is zero is termed  $\alpha_{L=0}$ , the zero-lift angle of attack. As the angle of attack is increased from  $\alpha_{L=0}$ , the lift increases linearly over a wide range of  $\alpha$ . The slope of this line is the *lift slope*. As  $\alpha$  becomes large, the pressure gradients on the upper surface of the airfoil also become large, and separation of the boundary layer occurs. Separation causes a large reduction in lift and the airfoil is said to be stalled. The maximum lift generated by the airfoil is indicated by  $C_{L,max}$ . Before the decrease in lift occurs, the curve becomes nonlinear because of viscous effects.

**Figure 172.7** Lift and moment coefficients as a function of angle of attack for the NACA 2412 airfoil.

In the linear region of the curve where viscous effects have a small impact on the lift, *thin airfoil theory* can be used to predict the airfoil behavior. If the airfoil thickness is small in comparison to its chord, the flowfield about the airfoil can be represented by distributing vortices along the mean camber line. An infinite number of solutions are possible for the distribution of the strengths of the vortices as a function of chord. All but one of these solutions is eliminated by applying the *Kutta condition*. The Kutta condition essentially requires that the flow be physically realistic in that the fluid cannot flow around a sharp trailing edge. More specifically, it states that the following be true: (a) the value of the circulation,  $\Gamma$ , is such that the flow leaves the trailing edge smoothly; (b) if the included angle at the trailing edge is finite, then the trailing edge is a stagnation point; and (c) if the trailing edge is cusped (zero included angle), then the velocities from the upper and lower surfaces are equal in magnitude and direction at the trailing edge. Thin airfoil theory then yields a lift slope of  $2\pi$ , so in the case of a symmetric airfoil  $C_L = 2\pi\alpha$ . For relatively thin airfoils, less than about 12%, this prediction is accurate to within several percent of experimentally determined values.

Camber controls the amount of lift generated at zero angle of attack. A symmetric airfoil (zero camber) generates no lift at  $\alpha = 0$ . An airfoil with positive camber generates lift at  $\alpha = 0$ , and zero lift occurs at a negative angle of attack, as shown in Fig. 172.7.

Figure 172.7 also shows the variation of moment coefficient with angle of attack for a typical cambered airfoil. The moment is usually taken about a point one quarter of the way along the chord line from the leading edge. This point is known as the *quarter-chord point*. Note that the value of the moment is negative, indicating that the moment acting on the airfoil tends to rotate it in the counterclockwise direction for the airfoil depicted in Fig. 172.6. Camber also affects the moment—a symmetric airfoil produces no moment and an increase in the camber causes an increase in the magnitude of moment.

In Fig. 172.7, the moment coefficient is approximately constant over a wide range of angle of attack. The quarter-chord point was chosen as the point about which to determine moments for specifically this reason—it is the *center of pressure* for an airfoil. The center of pressure is defined as the point about which the moment is constant, independent of angle of attack. Another useful point in aerodynamics is the *aerodynamic center*, which is the point about which the moment is zero. For a symmetric airfoil, this point happens to be also at the quarter-chord point. In general, the aerodynamic center may or may not lie on the body itself. As viscous effects become important, the moment varies from its ideal behavior, as did the lift behavior. Near stall, the magnitude of the moment increases because of boundary layer separation altering the static pressure distribution.

Drag data is usually presented as a function of lift coefficient, instead of angle of attack, in what is termed a *drag polar*. An example of a drag polar is shown in Fig. 172.8 for a cambered airfoil. This drag coefficient includes both the viscous and pressure drags. The penalty in drag for generating high lift coefficients is clear from Fig. 172.8. In addition, when the airfoil approaches stall, and the upper surface boundary layer separates, the drag increases dramatically. This increase is caused by the large pressure drag associated with separation, as indicated in section 172.2. In many applications, the ratio of lift to drag,  $L/D$ , is an important performance parameter. The  $L/D$ s of different airfoils can easily be compared using a drag polar simply by looking at the slope of a line drawn between a point on the polar and the origin of the plot.

**Figure 172.8** Drag polar for the NACA 2412 airfoil.

## 172.4 Finite Wing Effects

Two-dimensional, or infinite wing, performance was discussed in the previous section. Of course, all real aircraft have finite wings. In this section, the modification of infinite wing performance due to the finite nature of real wings is presented. The primary difference between the two cases is that, in the finite wing, the flow can be three-dimensional (i.e., flow can occur into and out of the paper in [Fig. 172.4](#) as well as in the plane of the paper). If a wing is generating lift, then the average pressure on the lower surface must be higher than that on the upper surface. Near the wing tips, this pressure difference causes flow from the lower surface to the upper surface, as shown in [Fig. 172.9](#). This leakage around the wing tips causes the flow to rotate about a streamwise axis as it leaves the wing tip, forming *wing tip vortices*, as shown in [Fig. 172.10](#). Inboard of the wing tips, the flow has a spanwise component due to the leakage around the wing tips. As shown in [Fig. 172.9](#), the flow over the lower surface tends to move out toward the wing tip, and the flow over the upper surface tends to move inboard. Clearly, the flow is not two-dimensional, as was assumed in the previous section.

**Figure 172.9** Finite wing effects.

**Figure 172.10** Wing tip vortices formed by a finite wing.

Wing tip vortices induce flow about their axes. In the region of the wing, it can be seen from [Fig. 172.9](#) that the resulting induced flow will be downward. This induced downward flow is termed *downwash* and locally rotates the incoming velocity vector, as shown in [Fig. 172.11](#). Locally, the angle of attack is reduced by  $\alpha_i$ . Thus, the effective angle of attack is  $\alpha_{\text{eff}} = \alpha - \alpha_i$ . Lift is generated perpendicular to the local freestream velocity, and as it has been rotated by  $\alpha_i$ , then the lift vector is also rotated by  $\alpha_i$ . The lift vector now has a component parallel to the freestream that is far from the wing,  $D_i$ —the *induced drag*. In summary, the downwash induced in the region of the wing by the wing tip vortices reduces the effective angle of attack of the airfoil section. This tilts the lift vector downstream, resulting in a component of lift acting in the drag direction. Typical airfoil sections might have a  $L/D$  ratio of about 100. Thus, only a small rotation of the large lift vector can cause a significant increase in drag, which appears as pressure drag.

**Figure 172.11** Diagram illustrating the tilting of the lift vector due to the downwash.

The induced drag of a wing depends on the downwash distribution along its span. It can be shown that the downwash distribution depends on the lift distribution across the wing span. Lift per unit span can vary for several reasons: (1) changes in chord; (2) changes in angle of attack; and (3) variations in airfoil shape. An elliptical distribution of lift across the span, as shown in [Fig. 172.12](#), provides a minimum induced drag. Lifting-line theory can be used to predict the downwash for an elliptical lift distribution and a detailed discussion of this technique can be found in Kuethe and Chow [1986]. In this case, the drag coefficient for the induced drag is

$$C_{D,i} = \frac{C_L^2}{\pi AR} \quad (172.12)$$

where  $AR$  is the *aspect ratio* of the wing defined as  $AR \equiv b^2/S$ . It can be seen from Eq. (172.12) that, as the aspect ratio increases (i.e., the wing becomes longer and more slender), the induced drag is reduced. This equation also indicates the dependence of induced drag on lift. As the lift increases, the strength of the tip vortices increases, and therefore the downwash increases, which causes the lift vector to tilt more in the downstream direction.

**Figure 172.12** Elliptical lift distribution over a finite wing.

In practice, it is difficult to obtain an elliptical lift distribution. Thus, the induced drag is higher than that for an elliptical distribution. In general,

$$C_{D,i} = \frac{C_L^2}{\pi e AR} \quad (172.13)$$

where  $e$  is the *span efficiency factor*. For elliptical wings,  $e = 1$ , but for typical subsonic aircraft,  $0.85 < e < 0.95$ . Thus, the total drag for a finite wing is the sum of the induced drag and the infinite wing drag:

$$C_{D,\text{tot}} = C_{D,2-D} + \frac{C_L^2}{\pi e AR} \quad (172.14)$$

In addition to affecting the drag of two-dimensional airfoil data, the finite nature of a wing also reduces the lift slope. The downwash reduces the effective angle of attack, and therefore reduces the lift generated. For a general wing, the effective angle of attack is

$$\alpha_{\text{eff}} = \alpha - \frac{57.3 C_L}{\pi e' AR} \quad (172.15)$$

where  $e'$  is another span effectiveness factor, which, in practice, is approximately equal to  $e$ . The reduced lift for a given angle of attack indicates a reduction in the lift slope,  $a$ , which becomes

$$a = \frac{a_0}{1 + 57.3 a_0 / (\pi e' AR)} \quad (172.16)$$

where  $a_0$  is the two-dimensional lift slope and  $a$  is the lift slope including finite wing effects.

## 172.5 Effects of Compressibility

It has been assumed to this point that the flow speed has been low enough that the effects of compressibility of the fluid have been negligible (Section VI describes compressibility in more detail and should be reviewed at this time if the reader is unfamiliar with this topic). However, as the freestream speed and thus the freestream Mach number ( $M_\infty$ ) are increased, compressibility effects are seen. Only a brief discussion of some of these effects is presented here.

If the local Mach number increases above 1.0, there exists the possibility for the formation of shock waves. This effect is one of the major differences between compressible and incompressible flows and is depicted in Fig. 172.13. Over the upper surface of an airfoil, the flow moves faster than the freestream. Thus, the Mach number in a region above the upper surface can be supersonic even if the freestream Mach number is less than one [see Fig. 172.13(c)]. The freestream Mach number at which the flow over the upper surface reaches Mach 1.0 is termed the *critical Mach number*,  $M_{\text{crit}}$ . As the freestream Mach number increases, a shock wave forms on the upper surface, causing boundary layer separation because of the strong adverse pressure gradient [see Fig. 172.13(d)]. In this case, the drag of the airfoil increases dramatically, as shown in Fig. 172.13(a). The Mach number where the drag begins to rise is the *drag divergence Mach number*,  $M_{\text{drag rise}}$ .

**Figure 172.13** Drag as a function of Mach number (a), and airfoil flowfields associated with the three Mach number ranges (b–d).

High-speed subsonic aircraft often have swept wings. The purpose of wing sweep is to increase  $M_{drag\ rise}$  so the aircraft can fly faster. By sweeping the wing back, the airfoil "sees" only the component of the freestream Mach number normal to the leading edge, which is lower than the total freestream Mach number, as shown in Fig. 172.14. Thus, the critical Mach number with sweep should be  $M_{cr, sweep} = M_{cr}/\cos \theta$ . In practice, because of the complex flowfield induced by wing sweep, the benefit of sweep is less than this. A more complete discussion of compressibility effects in aerodynamics can be found in Anderson [1984].

**Figure 172.14** The effect of wing sweep on the normal Mach number.

### WIND TUNNEL TESTING

The cornerstone of aerodynamics is wind tunnel testing. Here a model of the state-of-the-art Boeing 777 undergoes rigorous testing prior to the first flight of the actual Boeing 777 on June 12, 1994. This unique testing facility, the Transonic Dynamics Tunnel (TDT), is a national facility dedicated to aeroelastic research and engineering of high-speed aircraft and rotorcraft.

The TDT, a continuous-flow, closed-circuit, variable-density pressure tunnel, was completed in 1959. It is the world's first aeroelastic testing tunnel. It can test cable-mounted, sidewall-mounted, sting (strut)-mounted, or floor-mounted aircraft models. The test medium is Freon 12 or air. It operates in a speed range of up to Mach 1.2 (1.2 times the speed of sound) at pressures up to 350 lb/ft<sup>2</sup>. The TDT was designed to use Freon rather than air in order to achieve the desired tunnel test speed of Mach 1.2 at required pressure levels.

The principal focus of wind tunnel aeroelasticity studies today is "flutter." As an aircraft flies through the air, its wings and tail vibrate at certain frequencies, a harmless combination of structural responses to aerodynamic pressures. However, almost every aircraft is susceptible at certain speeds to a potentially harmful interplay of the wing vibrations and aerodynamic forces called flutter. In the most severe cases, unchecked flutter can damage or destroy a wing. Wind tunnel tests can identify a potential flutter problem, and changes can be made to the aircraft to make it safe to fly.

Future aircraft model tests in the TDT will ensure that new designs of high-speed aircraft and space vehicles are flutter free. (Photo courtesy of NASA, Langley.)

## Defining Terms

**Drag:** The net aerodynamic force on a body in a direction parallel to the freestream.

**Lift:** The net aerodynamic force on a body in a direction perpendicular to the freestream direction and to the wing platform.

**Vortex:** A flowfield in which fluid elements rotate about a common axis. In a vortex where viscous effects are not important, the velocity at which a fluid element circles the axis is inversely proportional to its distance from the axis.

**Wake:** The region of a flowfield downstream of a body where the momentum is less than that of the freestream.

#### **Ronald A. Hess**

*University of California*

The aerodynamic forces which allow the sustained flight of heavier-than-air vehicles are created by the relative motion of the aircraft and the fluid mass through which it moves. In the case of a nonquiescent atmosphere, the motion of the fluid mass itself contributes to this relative motion. Since the atmosphere is rarely quiescent, the subject of aircraft stability and control in a moving atmosphere is of considerable importance to aeronautical engineers from a standpoint of performance, passenger comfort, and safety.

## 173.1 Descriptions of Atmospheric Movement

---

### **Background**

The fundamental approach which physicists and engineers adopt in describing the motion of a continuum, such as the atmosphere, is a field description. The velocity of the atmosphere is considered to be a continuous function of location and time, referred to as a velocity field.

Consider Fig. 173.1, showing an orthogonal axis system fixed relative to the earth. At some points  $x_0$ ,  $y_0$ , and  $z_0$ , and at some time instant  $t_0$ , the three components of the velocity of the atmosphere are  $u_a(x_0, y_0, z_0, t)$ ,  $v_a(x_0, y_0, z_0, t)$ , and  $w_a(x_0, y_0, z_0, t)$ . The preceding description allows a convenient means of categorizing atmospheric motion.

**Figure 173.1** Axes systems for description of atmospheric movement.

### Mean Winds

If, for example,  $u_a = U$ ,  $v_a = V$ , and  $w_a = W$ , where  $U$ ,  $V$ , and  $W$  represent constants, one has defined a **mean wind**. Obviously, this is an idealized description, but nonetheless a useful one. For example, airliner flight in the jetstream can often be adequately described by such a mean wind condition.

### Wind shears

If, for example,  $u_a = u_a(x)$ ,  $v_a = V$ , and  $w_a = W$ , one has defined a simplified **wind shear**—a velocity field in which the velocity varies with position, but not with time. Here, the changes in  $x$  ( $\Delta x$ ) over which significant changes in  $u_a$  occur are assumed to be such that  $\Delta x \gg l_f$ , where  $l_f$  represents the aircraft fuselage length.

### Turbulence

If, for example,  $u_a = U$ ,  $v_a = V$ , and  $w_a = w_a(x, t)$ , and if the changes  $\Delta x$  over which significant changes in  $w_a$  occur are such that  $\Delta x$  is the same order of magnitude as  $l_f$ , one has defined atmospheric **turbulence** or **gusts**. If, as in Fig. 173.1, the direction of the  $w_a$  axis has been chosen to be vertical, the field just described is referred to as a vertical turbulence field or a one-dimensional *upwash* field [Etkin, 1972].

The intensity of turbulence is typically quantified by the **root mean square (RMS) value** of each of the components. Thus, at some point  $x_0$  in the one-dimensional upwash field,

$$\sigma_{w_a} \triangleq \text{RMS value of } w_a(x_0, t) = \sqrt{\lim_{T \rightarrow \infty} \frac{1}{2T} \int_{-T}^T w_a^2(x_0, t) dt} \quad (173.1)$$

### Simplified Descriptions

Concentrating upon turbulence, it is often assumed in aircraft stability and control analyses that the statistical description of the turbulence field (e.g., the RMS velocity at a point) is not a function of time, the origin, or the orientation of the axis system used to describe the field. If, as is typically the case, the aircraft is moving through the field with a velocity that is significantly larger in magnitude than the RMS value of the turbulence velocity at any point along its path, then the

spatial and temporal variation of the turbulence field may be replaced by the spatial variation alone. Thus,  $w_a(x, t) = w_a(x)$ . This is referred to as a **frozen turbulence field hypothesis** or **Taylor's hypothesis** [Houbolt, 1973].

## 173.2 Turbulence and Aircraft Dynamics

Figure 173.2 is a representation of an aircraft flying through the one-dimensional frozen upwash field described in the preceding section. The velocity profile of the turbulence field is represented in the figure, with the vertical arrows indicating the magnitude and direction of the atmospheric velocity at each point on the idealized linear flight path. The problem now becomes one of determining the aerodynamic forces and moments that are created on the aircraft by the indicated turbulence velocities. To do this, a mathematical description of the frozen turbulence field,  $w_a(x)$ , is needed.

**Figure 173.2** Aircraft in a one-dimensional, frozen upwash field.

### Fourier Integral Representation

It is often assumed that  $w_a(x)$  is a sample function from an ergodic random process [Bendat and Piersol, 1966]. An important measure associated with such sample functions is the autocorrelation function, defined as

$$\phi_{w_a w_a}(\xi) = \lim_{X \rightarrow \infty} \frac{1}{2X} \int_{-X}^X w_a(x) w_a(x - \xi) dx \quad (173.2)$$

The autocorrelation function has a Fourier Integral or Fourier Transform representation:

$$\begin{aligned}\phi_{w_a w_a}(\xi) &= \frac{1}{2\pi} \int_{-\infty}^{\infty} \Phi_{w_a w_a}(\Omega) e^{j\xi\Omega} d\Omega \\ \Phi_{w_a w_a}(\Omega) &= \int_{-\infty}^{\infty} \phi_{w_a w_a}(\xi) e^{-j\xi\Omega} d\xi\end{aligned}\quad (173.3)$$

Here,  $\xi$  represents spatial frequency with units of rad/ft or rad/m.  $\Phi_{w_a w_a}(\Omega)$  is referred to as the **power spectral density** of  $w_a(x)$ . Power spectral density representation constitutes one of the primary ways in which the characteristics of atmospheric turbulence have been measured and reported [Houbolt, 1973].

Two power spectral forms widely used in turbulence analyses are the von Karman and Dryden spectra [Etkin, 1972]. For example, the von Karman spectrum is given by:

$$\Phi_{w_a w_a}(\Omega) = 2\sigma_{w_a}^2 L \frac{1 + \frac{8}{3}(1.339L\Omega)^2}{[1 + (1.339L\Omega)^2]^{\frac{11}{6}}}\quad (173.4)$$

where  $L$  is referred to as the **turbulence scale length**. Depending upon altitude and turbulence intensity, scale lengths from 200 to 5000 ft have been measured [Houbolt, 1973]. Often in flight control system analysis, a spectrum simpler in form than those of Eq. (173.4) is used. For example,

$$\Phi_{w_a w_a}(\Omega) = 2\sigma_{w_a}^2 L_{w_a} \frac{1}{1 + (L_{w_a}\Omega)^2}\quad (173.5)$$

If one limits the spatial duration of  $w_a(x)$  to a large but finite value,  $X$ , then  $w_a(x)$  is itself amenable to representation by a Fourier Integral or Fourier Transform as

$$w_a(x) = \frac{1}{2\pi} \int_{-\infty}^{\infty} W_a(j\Omega) e^{j\Omega x} d\Omega\quad (173.6a)$$

$$W_a(j\Omega) = \int_{-\infty}^{\infty} w_a(x) e^{-j\Omega x} dx\quad (173.6b)$$

Equation (173.6a) can be used to show that  $w_a(x)$  may be envisioned as the sum of an infinite number of sinusoids, each of infinitesimal amplitude, with the frequency of each constituent sinusoid differing only infinitesimally from sinusoid to sinusoid [McRuer *et al.*, 1973].

## Aerodynamic Force/Moment Prediction

The problem of determining the aerodynamic forces and moments exerted on an aircraft as it moves through an upwash field can be simplified as follows. Compare the magnitudes of  $l_f$  and the spatial wavelengths ( $2\pi/\xi$ ) of the constituent infinitesimal sinusoids of  $w_a(x)$ . Consider the

case where  $w_a(x)$  has the majority of its power below a frequency  $\omega_0$ . If  $l_f \leq 8(2\pi/\omega_0)$ , the variation in  $w_a(x)$  over the length of the aircraft can be considered to be linear. This is shown in Fig. 173.2. The relationship  $l_f \leq 8(2\pi/\omega_0)$  is derived from the simple fact that a straight line can be considered an adequate approximation to a sinusoid if the length of the line is less than one-eighth of the period (wavelength) of the sinusoid.

Figure 173.2 suggests that the relative motion of the aircraft and upwash field (and the aerodynamic forces and moments being produced) is, at this instant, equivalent to that which would be in evidence if the aircraft were moving through quiescent air but with an instantaneous vertical velocity component

$$w(t) = -w_a(x_{cg}) \quad (173.7)$$

and an instantaneous angular pitching velocity (pitch rate) of

$$q(t) = \frac{dw_a(x_{cg})}{dx} = \frac{1}{U_0} \frac{dw_a(x_{cg})}{dt} \bigg|_{x_{cg}=U_0 t} \quad (173.8)$$

Here  $x_{cg}$  refers to the  $x$  coordinate of the aircraft center of gravity in the  $xyz$  axis system used to describe the frozen turbulence field.

The manner in which turbulence effects are included in the aircraft equations of motion can now be described. The force equations can be written in the familiar form:

$$\mathbf{F} = m \frac{d\mathbf{v}}{dt} \quad (173.9)$$

where  $\mathbf{F}$  represents the vector sum of the aerodynamic and propulsive forces acting on the aircraft of mass  $m$ , and  $\mathbf{v}$  represents the velocity vector of the aircraft's center of gravity.

For aircraft applications, Eq. (173.9) is typically linearized about a condition of steady, wings-level flight [Etkin *et al.*, 1972]. The components of  $\mathbf{F}$  in this equation are expressed as linear functions of the aircraft's linear and angular velocity perturbations and their derivatives. Thus, for example, referring to Fig. 173.1, the  $x_b$  and  $z_b$  body axis component of  $\mathbf{F}$  can often be simplified to

$$F_x = m[-g(\cos \theta_0)\Delta\theta + X_u\Delta u + X_w\Delta w + X_\delta\Delta\delta] \quad (173.10a)$$

$$F_z = m[-g(\sin \theta_0)\Delta\theta + Z_u\Delta u + Z_{\dot{w}}\Delta\dot{w} + Z_w\Delta w + Z_q\Delta q + Z_\delta\Delta\delta] \quad (173.10b)$$

where  $\Delta\theta$ ,  $\Delta u$ ,  $\Delta w$ , and  $\Delta\delta$  represent, respectively, perturbations in the pitch attitude, the components of  $\mathbf{v}$  in the aircraft's  $x_b$  and  $z_b$  body axes, and control/propulsive inputs.  $X$  and  $Z$  represent the components of the aerodynamic and propulsive forces in the  $x_b$  and  $z_b$  body axis directions. The quantities  $X_u$ ,  $X_w$ , etc., are referred to as mass normalized stability derivatives [McRuer *et al.*, 1973]. Equation (173.10) can now be modified to include the effects of the

one-dimensional upwash field by simply replacing  $\Delta w$  with  $(\Delta w - w_a)$  and  $\Delta q$  with  $[\Delta q + (\dot{w}_a/U_0)]$ . The result will be the addition of a disturbance term to Eqs. (173.10a) and (173.10b).

### 173.3 An Example

It is useful at this juncture to consider a simple flight control example utilizing the modeling procedure outlined in the previous paragraphs. Consider a small business jet flying at an equilibrium velocity of 677 ft/s (Mach No. = 0.7) at 40 000 ft and encountering a one-dimensional upwash field with a power spectral density described by Eq. (173.5). The turbulence intensity is  $\sigma_{w_a} = 10$  ft/s, and the scale length is  $L = 2000$  ft. The response variable of interest in this analysis is the normal acceleration at the aircraft's center of gravity,  $a_{z_{cg}}(t)$ . With the frozen turbulence assumption, the RMS value of  $a_{z_{cg}}(t)$  is given by

$$\sigma_{a_{z_{cg}}} = \sqrt{\lim_{T \rightarrow \infty} \frac{1}{2T} \int_{-T}^T a_{z_{cg}}^2(t) dt} = \sigma_{a_{z_{cg}}} = \sqrt{\frac{1}{2\pi} \int_{-\infty}^{\infty} \Phi_{a_z a_z}(\omega) d\omega} \quad (173.11)$$

where

$$\Phi_{a_z a_z}(\omega) = \left| \frac{a_{z_{cg}}}{w_a}(j\omega) \right|^2 \Phi_{w_a w_a}(\omega) = \left| \frac{a_{z_{cg}}}{w_a}(j\omega) \right|^2 \left[ \frac{1}{U_0} \Phi_{w_a w_a}(\Omega) \right]_{\Omega = \frac{\omega}{U_0}} \quad (173.12)$$

and where  $a_{z_{cg}}/w_a(s)$  is obtained from the vehicle equations of motion, modified with turbulence terms as just described.

The aircraft possesses an autopilot designed to maintain a desired or equilibrium value of normal acceleration. Figure 173.3 shows  $\Phi_{a_z a_z}(\omega)$  for the aircraft, with and without the autopilot. The temporal frequency corresponding to a spatial wavelength eight times  $l_f$  is also shown. The RMS value of  $a_{z_{cg}}(t)$  for the aircraft with control system is approximately 2.8 ft/s<sup>2</sup>.

**Figure 173.3** Normal acceleration power spectral densities for aircraft in example problem.

## 173.4 Other Applications

---

The modeling technique which has been outlined is applicable to more complex turbulence fields than the simple upwash field discussed here. Extension to two-dimensional fields is, of course, possible. In addition, the effects of atmospheric movement other than random turbulence, such as flight through microbursts, is obviously possible [Psiaki and Stengel, 1985]. This type of low-altitude meteorological phenomenon produces large wind shears and can be particularly dangerous to an aircraft in takeoff and landing [Wingrove and Bach, 1989].

### Defining Terms

**Frozen turbulence field (Taylor's hypothesis):** A hypothesis that considers the time and spatial variation of the atmospheric velocities of a turbulence field as a spatial variation only.

**Mean wind:** A constant atmospheric velocity, independent of location and time.

**Power spectral density:** A means of describing the distribution, with frequency, of the power in a signal.

**Root mean square (RMS) value:** The square root of the integral of a squared function, divided by the integration interval.

**Turbulence (gusts):** The rapid, random variations of atmospheric velocities at a point in a space.

**Turbulence scale length:** A parameter appearing in the power spectral density representation of a frozen turbulence field. It is related reciprocally to the break frequency of the power spectral density (i.e., the larger the characteristic length, the lower the spatial or temporal break frequency).

**Wind shear:** The variation in atmospheric velocity as a function of location, often associated with microbursts.

174.1 Geometry Modeling and Grid Generation

174.2 Flow Simulation Algorithms

174.3 Turbulence Modeling

174.4 Flow Simulation Examples

174.5 Future Directions and Challenges

**Ramesh K. Agarwal**

*Wichita State University*

In the past two decades, enormous progress has been made in computational methods for the study of fluid flow phenomena in a broad variety of scientific and engineering disciplines. Examples include aircraft, ship, and automobile design; oceanography; meteorology; and astrophysics. The focus of this chapter is, however, on computational aerodynamics, which is rapidly emerging as a crucial enabling technology for the analysis and design of flight vehicles. Computational simulations, coupled with targeted experimental testing, have proven to be a cost-effective way of developing flight vehicles. Such combined evaluations are performed to ensure that the final product will efficiently meet target performance characteristics, using few design cycles. On the other hand, for some flight regimes, such as hypersonic flows at high altitude, experimental testing may not be feasible, and in such cases even greater reliance is placed on computational simulations.

In aeronautical applications, the computational analysis of the aerodynamic performance of a flight vehicle—be it an aircraft, a helicopter, or a launch vehicle—is a multistep process. First, a geometric description of the configuration is obtained in discretized form. Second, a grid is generated around the object to provide a finite set of points over which the flow field solution is calculated. The flow is then solved, and enormous quantities of data for pressure, temperature, and velocity variables are processed to obtain the aerodynamic quantities of interest—namely, the lift, drag, moment coefficients, and other parameters required to assess the flight vehicle performance.

In this respect, recent developments in computational fluid dynamics primarily fall into two broad categories: (a) computational prediction of the flow field about increasingly complex configurations, and (b) the simulation of flow physics leading to a better understanding of such flow phenomena as transition and turbulence. This chapter covers only the first category: the computational tools employed in aerodynamic analysis and their application in analyzing the aerodynamic performance of complex configurations.

### 174.1 Geometry Modeling and Grid Generation

---

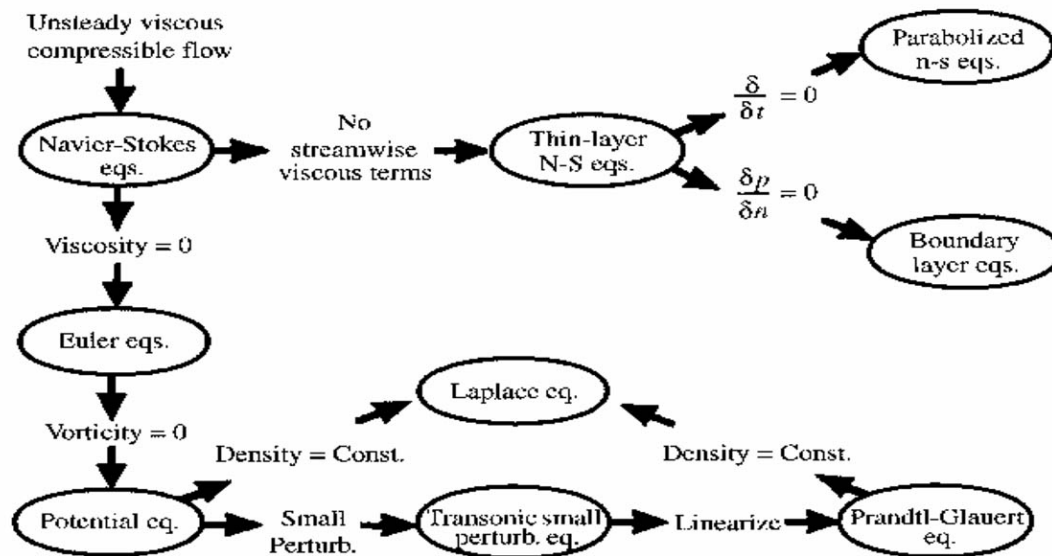

In the aerospace industry, the geometric description of the configuration in discretized form is routinely created using computer-aided-design (CAD) systems. However, the generation of a suitable three-dimensional grid about complete aircraft configurations remains a formidable task. In this respect, there have been significant developments in the past decade, with both the algebraic and partial differential equations–based techniques fairly well developed for the generation of

structured global grids about complex three-dimensional shapes. The recent thrust has been toward zonal grids and unstructured grid technologies since they are thought to be more effective for treating flows over complex three-dimensional objects. In addition, there have been major advances in adaptive grid and grid embedding techniques, for optimal distribution of grid points around an object in order to resolve sharp gradients and discontinuities, at the least cost possible. A review article by Steinbrenner and Anderson [1990] appropriately describes these developments.

## 174.2 Flow Simulation Algorithms

For flow field solutions, mathematical models vary in complexity from the simple Laplace equation to the unsteady compressible Navier-Stokes equations. Figure 174.1 describes the equations of fluid dynamics for mathematical models of varying complexity.

**Figure 174.1** Equations of fluid dynamics for mathematical models of varying complexity.

During the late 1960s, panel methods were developed for calculating inviscid subsonic flow about complex aerodynamic shapes by solving the Laplace equation. Also, boundary-layer solution techniques were developed to allow for viscous effects, primarily for attached flows. During the early 1970s, a major breakthrough was achieved by Murman and Cole [1971], who solved the mixed elliptic-hyperbolic transonic small-disturbance equation. Later, Jameson [1974] extended the Murman-Cole technique to the solution of the transonic full-potential equation. Such codes are routinely used in transport aircraft design and have proven to be an effective tool, when combined with boundary-layer corrections, for predicting the aerodynamic performance of a variety of flight vehicles in the transonic range.

Most of the recent progress in the development of numerical algorithms has been for the solution of the Euler and Navier-Stokes equations, especially the development of efficient and accurate shock-capturing algorithms. Central-difference algorithms with artificial viscosity (dissipation), characteristics-based upwind schemes, and total-variation-diminishing schemes have been developed for hyperbolic conservation laws. Strong discontinuities (shocks) are captured by these schemes with little oscillation and minimal dispersive and dissipative errors. It is beyond the scope of this chapter to provide details of these techniques, and the reader is referred, for example, to a survey paper by Jameson [1990].

### SCRAMJET EXHAUST

SCRAMJET engine exhaust is modeled in this supercomputer-generated image of an aerospace vehicle as part of the National Aero-Space Plane (NASP) program. Contour lines which ring the airplane indicate air density away from the surface at selected points. Shadings on the aircraft indicate areas of highest air density.

Researchers at NASA's Langley Research Center, Hampton, VA, are studying engine nozzle performance and exhaust effects on tail control surfaces. The image simulates wind tunnel test conditions at Mach 10 (approx. 6500 mph).

NASP was a joint program between the Department of Defense, NASA, and U.S. industry that made great strides in demonstrating technology for an aerospace vehicle that would take off horizontally like an airplane, accelerate to 17000-plus miles per hour and reach low earth orbit (generally less than 300 miles altitude). Once in orbit, such a vehicle could deploy payloads, pick up or repair satellites, or visit space station *Freedom* before returning to earth for a runway landing. (Photo courtesy of National Aeronautics and Space Administration.)

## 174.3 Turbulence Modeling

---

The currently intractable problem of accurately and practically modeling turbulence effects must be addressed before computational aerodynamics becomes a reliable routine prediction tool for flow situations where viscous effects are dominant. Examples of such situations include separated flows over control surfaces at high angles of attack and aerodynamic heating on high-speed vehicles. The computation of the effect of turbulence from first principles remains an elusive goal at the present time, even for simple two-dimensional shapes such as airfoils, and using maximum available computing power.

In current aerodynamic analyses, turbulence effects are accounted for by phenomenological models. The time-averaged form of the Navier-Stokes equations (known as the Reynolds-averaged Navier-Stokes equations) are solved. Time-averaging introduces the turbulent Reynolds stresses in the Navier-Stokes equations, and these are calculated by multiplying an eddy-viscosity coefficient with the strain-rate tensor. The phenomenological description of eddy viscosity is known as "turbulence modeling." At present, there is no universal turbulence model which works for all flow situations. Generally, turbulence models are developed by validating them against experimental data for simple flow situations, and are then used for calculation of complex flow fields. This approach introduces an element of uncertainty into the prediction of complex flows.

A variety of turbulence models of varying complexity have been developed over the last half-century. The underlying theoretical framework behind these models and their range of applicability are not given here, but an interested reader can find a comprehensive discussion in a review paper by Rubesin [1987].

## 174.4 Flow Simulation Examples

---

The selected flow simulation examples given here basically draw upon the author's own work and that of co-workers at the McDonnell Douglas Research Laboratories. The purpose of these examples is to illustrate the current state in computational aerodynamics for the prediction of aircraft, launch vehicle, and helicopter flow fields, from a manufacturer's point of view.

Figure 174.2 shows the surface grid on a complete twin-jet transport aircraft. Figure 174.3 shows the pressure distribution on the aircraft at a cruise Mach number of 0.76 and angle of attack of  $2^\circ$  obtained with the Euler code described by Deese and Agarwal [1988]. Figure 174.4 shows the comparison of the computed pressure distribution, at various spanwise locations of the wing, with experimental data. The inviscid Euler solution tends to predict shocks which are too strong and too far downstream on the wing upper surface. Addition of the viscous terms moves the shock location and strength toward better agreement with the experimental data, except in the region near the suction peak, where better grid resolution is needed to capture the high flow field gradients. Figure 174.5 shows the surface grid on a complete fighter aircraft with faired inlets. Figure 174.6 shows the pressure distribution on the aircraft at a Mach number of 0.90 and an angle of attack of  $4.84^\circ$ , obtained with an Euler code described in Deese and Agarwal [1988]. Figure 174.7 shows the comparison of the computed and experimental pressure distributions at various spanwise locations of the fighter wing. The Euler solution tends to predict a suction peak higher than that observed experimentally. Better resolution of the relatively small-radius fighter wing should improve the

agreement with data. The shocks on the wing upper surface are predicted to be stronger and slightly downstream of the measured shocks, as is typical of inviscid solutions.

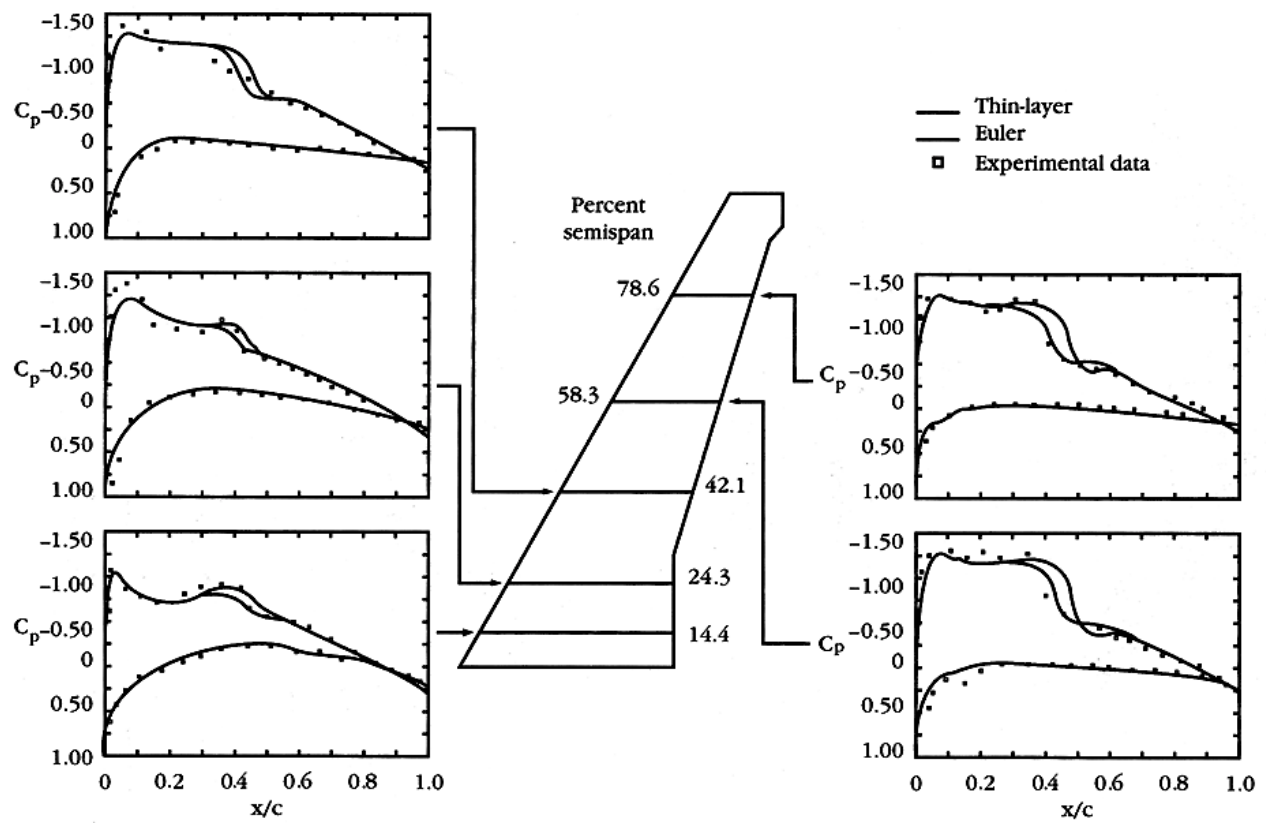

**Figure 174.2** Surface grid over a complete twin-jet aircraft.

**Figure 174.3** Euler solution predictions of surface pressure on a generic twin-jet transport aircraft;  $M_\infty = 0.76$ ,  $\alpha = 2.0^\circ$ .

**Figure 174.4** Comparison of Euler and thin-layer Navier-Stokes pressure distribution with experimental data for typical transport wing-body at  $M_\infty = 0.76$ ,  $Re = 6.39 \times 10^6$ ,  $\alpha = 2.0^\circ$ ,  $160 \times 34 \times 42$  mesh.

**Figure 174.5** Surface grid on a generic fighter with faired inlets.

**Figure 174.6** Surface pressure distribution on the generic fighter, Mach 0.9,  $\alpha = 4.84^\circ$ .

**Figure 174.7** Surface pressure distribution on the wing of the generic fighter;  $M = 0.9$ ,  $\alpha = 4.84^\circ$ .

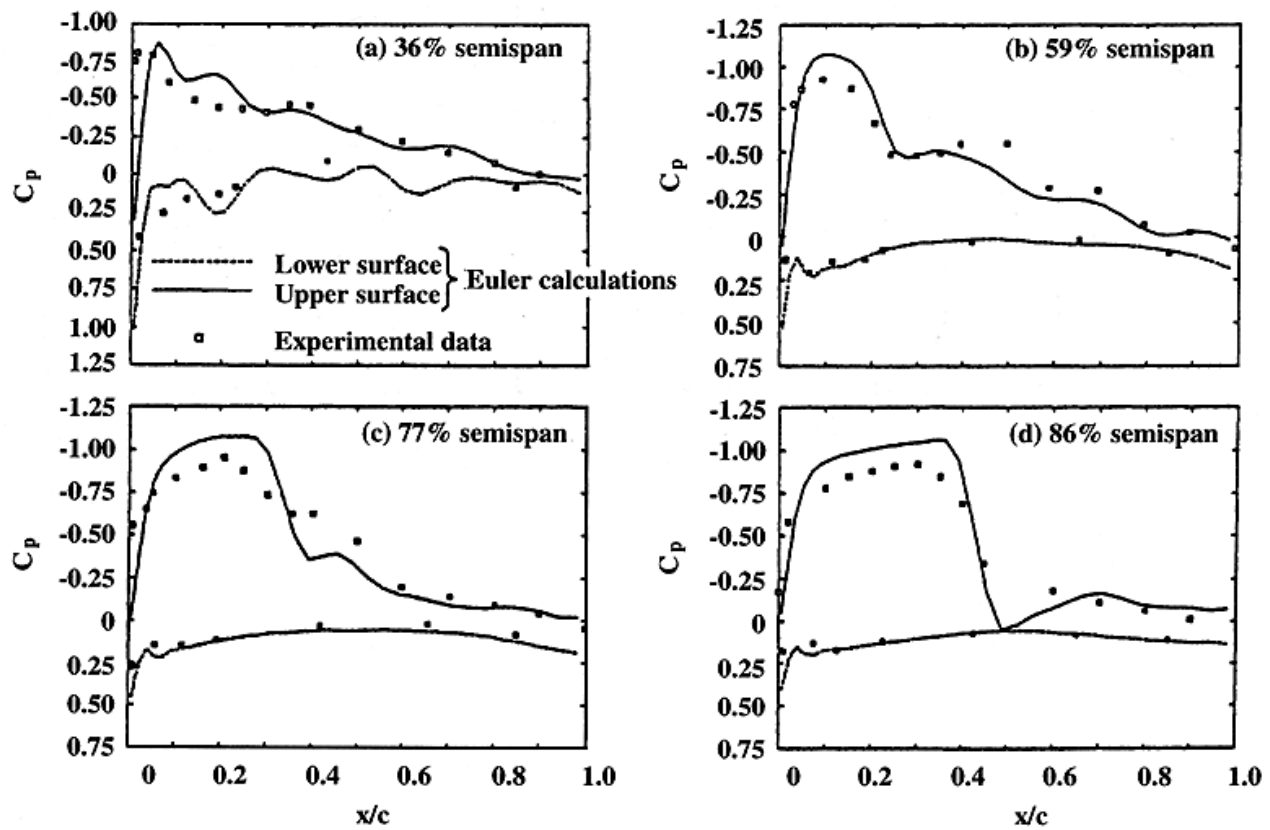

Figure 174.8 shows the surface grid on a launch vehicle with two boosters. Figure 174.9 shows the comparison of the computed pressure distribution on the main vehicle of a two-booster configuration with experimental data. The predictions are in good agreement with the data, except for the region just upstream of the booster nose. Inclusion of viscous effects should improve the agreement between the calculations and the experimental data.

**Figure 174.8** Surface grid over a launch vehicle with two boosters.

**Figure 174.9** Surface pressure distribution on the core of a launch vehicle with two boosters;  $M_\infty = 1.05$ ,  $\alpha = 0.0$ .

Figure 174.10 shows the grid distribution in the symmetry plane for a generic helicopter fuselage. Figure 174.11 shows the pressure distribution on an isolated helicopter fuselage obtained with the Navier-Stokes code described by Deese and Agarwal [1988]. Figure 174.12 shows the pressure distribution on an ONERA rotor blade in forward flight, obtained with the rotary-wing Euler code described by Agarwal and Deese [1987]. Figure 174.13 compares computed and experimental pressure distributions on the ONERA rotor in forward flight.

**Figure 174.10** Grid distribution in the symmetry plane for a generic helicopter fuselage.

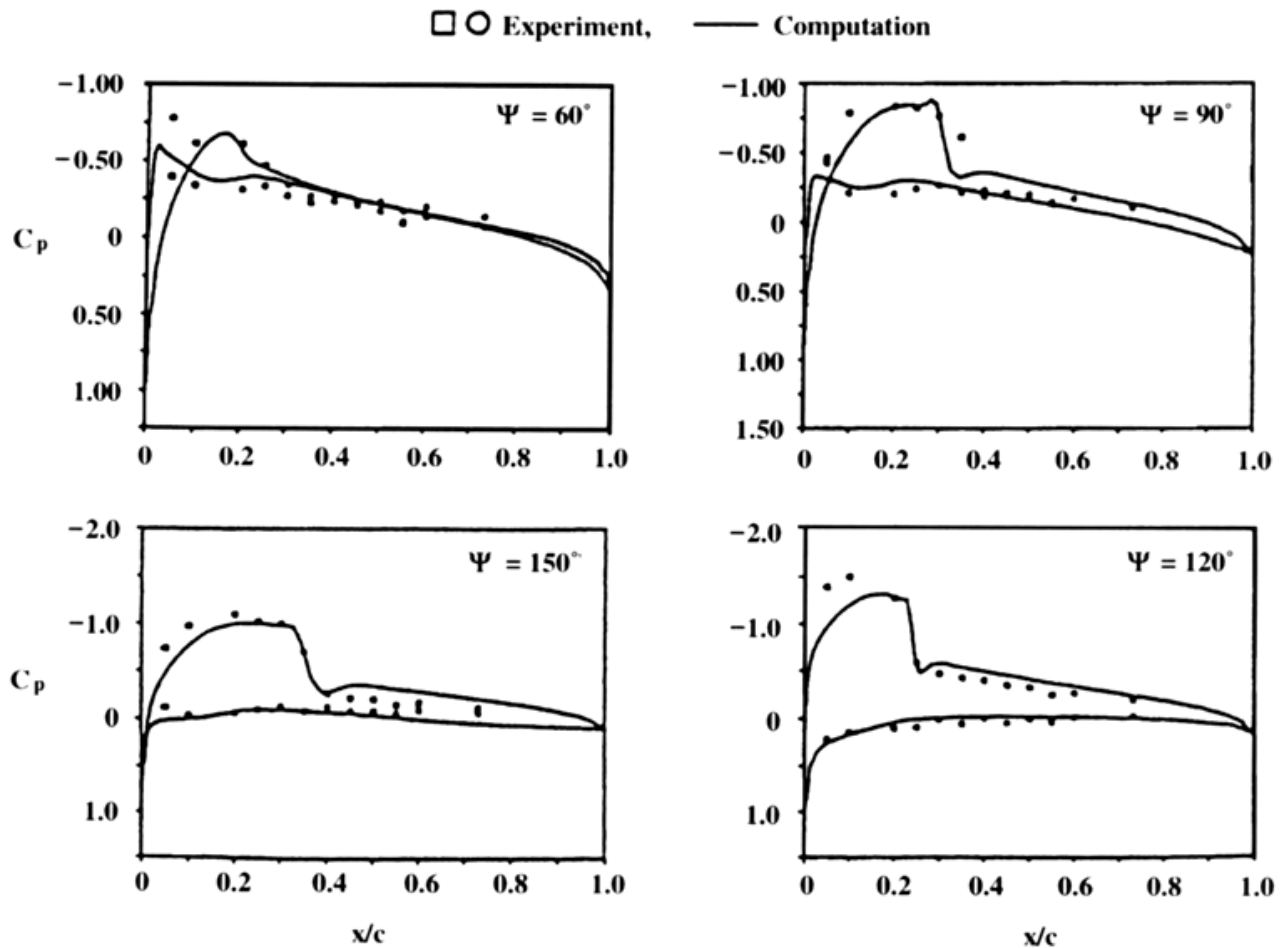

**Figure 174.11** Pressure distributions computed by the Navier-Stokes code on the symmetry plane of a generic fuselage configuration;  $M_\infty = 0.4$ ,  $\alpha = -5^\circ$ .

**Figure 174.12** Euler solutions for flow about an ONERA three-bladed rotor in forward flight;  $M_t = 0.629$ ,  $\mu = 0.388$ .

**Figure 174.13** Comparison of predicted and experimental rotor surface pressure distributions for the ONERA three-bladed rotor in forward flight;  $M_t = 0.629$ ,  $\mu = 0.388$ , 90% span location.

As a final example, [Fig. 174.14](#) shows the unstructured grid about an ONERA M6 wing. [Figure 174.15](#) shows the computed pressure distribution on the wing at various spanwise locations and its comparison with experimental data. These calculations were performed with the Navier-Stokes code described by Marcum and Agarwal [1990].

**Figure 174.14** Surface grids for ONERA M6 wing grid with 231507 elements and 42410 nodes. (a) Wing surface with 15279 faces and 7680 nodes. (b) Symmetry plane with 1525 faces and 813 nodes.

**Figure 174.15**  $C_p$  distribution for ONERA M6 wing at  $M_\infty = 0.84$ ,  $\alpha = 3.06^\circ$ , as predicted by the unstructured grid code.

Many examples of a similar kind exist in the aerospace literature, showing the power of computational aerodynamics in simulating flows about complex configurations.

## 174.5 Future Directions and Challenges

---

As we step into the second half of the 1990s, we can look back on the progress in computational aerodynamics during the 1970s, 1980s, and early 1990s with great satisfaction. At present, we can generate three-dimensional grids about complete vehicle configurations and employ efficient and accurate numerical algorithms for the solution of the Euler and Navier-Stokes equations. Inviscid flow can be computed quite accurately over the entire Mach number range.

However, confidence in the predictive capability of computational codes for viscous-dominated flows remains low because of turbulence model limitations and insufficient computing power. Furthermore, although significant advances have taken place in the analysis of flow fields, their impact on the development of direct design methods has been limited. The development of inverse design techniques has lagged far behind that of analysis tools. In the future, a strong emphasis is needed on the development of such design methods.

The next computational challenge will be in developing methods and techniques for multidisciplinary design optimization, that is, to include several disciplines simultaneously in the design optimization process, rather than in a sequential manner. A configuration could be optimized taking into account aerodynamic, structural, and signature constraints simultaneously.

Finally, two of the emerging computer-related technologies, artificial intelligence and massively parallel technology, are likely to have major impacts on flight vehicle design. Expert system technology will have a substantial impact on automating the design process, thus reducing the cost and time of a design cycle. Massively parallel technology will make real-time interactive analysis possible, opening up great opportunities for real-time design modifications and improvements in product quality, at a substantially reduced cost.

175.1 System Requirements and Materials Selection

175.2 Design Considerations

175.3 Nonstructural Materials

175.4 The Future

**Reid R. June**

*The Boeing Company*

Aerospace structural materials include aluminum, titanium, steel- and nickel-based alloys, and fiber reinforced plastics. Nonstructural materials include paint, rubber, transparencies, sealants, lubricants, wiring and electronics, and systems fluids. All aerospace materials must satisfy stringent performance requirements at minimum weight and cost.

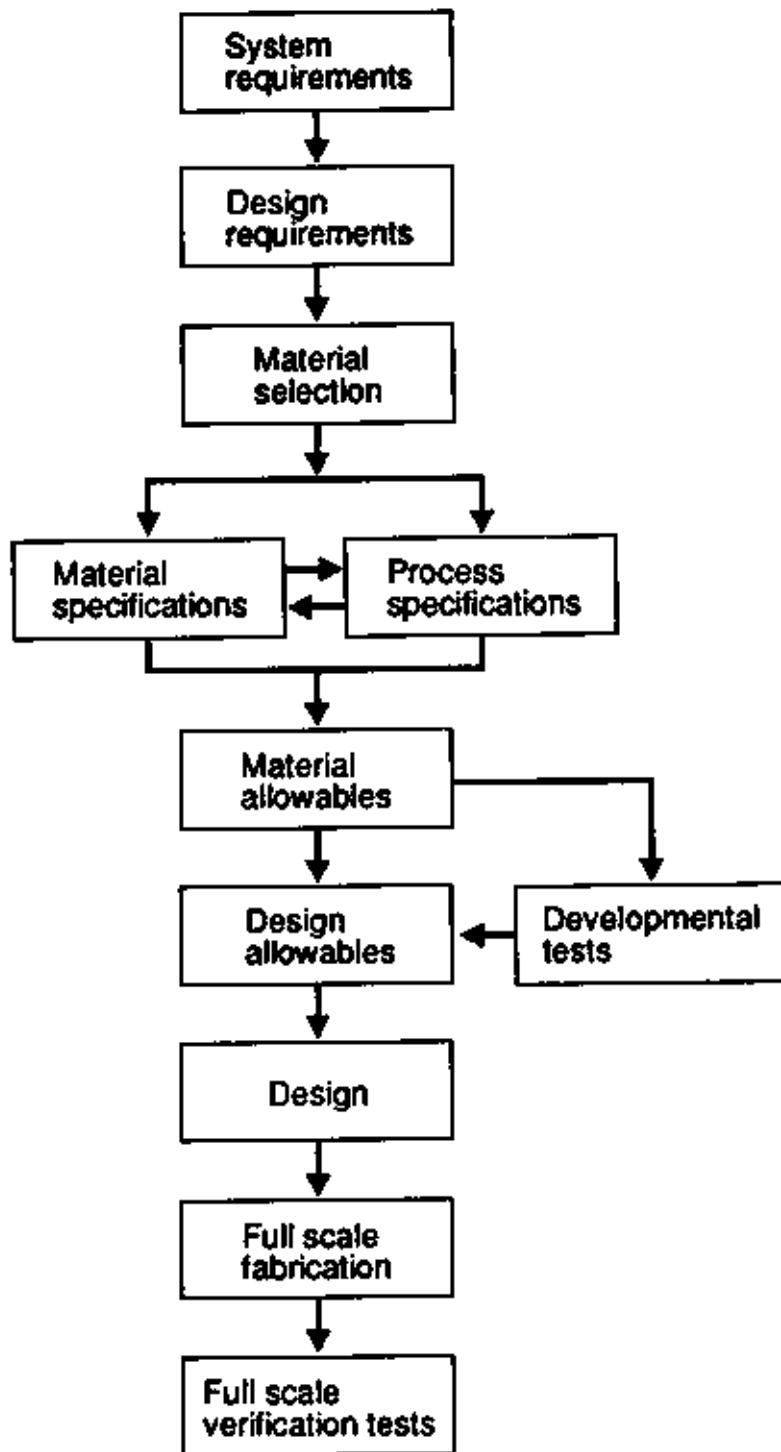

## **175.1 System Requirements and Materials Selection**

---

Aerospace materials selection begins with a thorough understanding of the design requirements for the system to which the materials are to be applied. Design requirements include loads, criteria, and operating environment. Crichlow [1969] presents an excellent approach for integrating structural requirements and material selection.

Figure 175.1 shows that system and design requirements drive materials selection. It is essential that all critical design requirements be understood as early in the design process as possible to enable the materials job to be done correctly the first time, thereby avoiding costly redesign and rework. Product development teams, where all disciplines are concurrently involved in design evolution, and expanded use of computer-aided design and manufacturing have helped to achieve this objective.

**Figure 175.1** Flow of system requirements through verification testing.

When the designers understand the materials requirements, the selection process can proceed with off-the-shelf materials or the development of new materials, if required. Most new systems include a combination of proven materials and new materials and processes developed to (1) improve performance, producibility, or both, (2) to satisfy unique requirements of the system, or

(3) to solve problems with earlier materials, such as excessive maintenance costs. Customer input is essential in this regard. In all cases, comprehensive materials and process specifications are written, usually in conjunction with material suppliers, to ensure that maximum advantage is taken of existing experience and knowledge.

Next, needed **material allowables** data are developed. For structural materials, these data typically include strength, modulus of elasticity, effects of temperature and environment, fatigue, toughness, corrosion resistance, and any other special data required for design of the system. The data are obtained from coupon tests. Design allowables are derived from material allowables and provide allowance for scale-up effects and uncertainties in materials, analysis, loads, and other system requirements. Design, fabrication, and test of full-scale test articles verify that design requirements are satisfied. If testing shows that requirements are exceeded, the design will accommodate growth in system performance parameters. If premature failure occurs, root causes must be identified and corrected.

Some materials have proven to be unsatisfactory in particular service applications. This condition is often traceable to inadequate development and testing prior to production, to discovery of material behavior that became evident only after several years of exposure to the service environment, or to systems operational conditions that were not identified in the original requirements. These failures underscore the importance of having accurate and complete requirements and obtaining the critical information to ensure that they are satisfied prior to entering production.

Aerospace system performance requirements demand the highest standards of quality from all elements of the system, including materials and related processes. Process standards, including **control limits**, must be established and followed during development, production, and operation of the system. Material suppliers, system manufacturers, and system operators all have responsibilities for maintaining process control during the system life cycle.

## 175.2 Design Considerations

---

Design concept, design criteria, material characteristics and processing, and operator maintenance all play key roles in ensuring structural integrity over the service life of the system. Metallic materials, for example, must have crack growth characteristics that ensure that normal inspections will reveal any crack before it can grow to a size that will jeopardize structural integrity. Advanced composite structures are designed so that damage will be detectable before structural integrity is compromised.

Minimum weight is essential in all aerospace systems. Materials with low specific weights or densities are key to lightweight structures. For this reason, aluminum alloys with densities of about 0.1 lb/in.<sup>3</sup> are widely used, comprising, for example, 60 to 70% of the structural weight of modern commercial aircraft. Lighter still are **advanced composite materials** with densities of about 0.06 lb/in.<sup>3</sup>. These materials offer 20 to 25% weight savings compared to aluminum structures and have excellent corrosion and fatigue characteristics. Mechanical property ranges for some widely used aerospace metals and composites are shown in [Tables 175.1](#) and [175.2](#), respectively. It should be noted that composite materials are continuing to evolve, especially for high-temperature applications. The ranges shown in [Table 175.2](#) are expected to change significantly over time.

**Table 175.1** Range of Mechanical Properties for Typical Aerospace Metallic Materials

Material	Density (pci)	Range of mechanical properties				Maximum Service Temp. (deg F)	Selection Drivers	Applications
		Modulus of Elasticity (msi)	Ultimate Tensile Strength (ksi)	Compressive Yield Strength (ksi)	Fracture Toughness (ksi √in)			
Aluminum								
2000-series	0.100–0.103	10.2–10.7	41–70	23–50	20–40	200–400	Fatigue, toughness	Lower wing structure, fuselage skins
7000-series	0.101–0.102	10.1–10.3	54–88	43–85	25	200	Strength	Upper wing structure, fittings, and structure
6000-series	0.098	9.9	26–42	12–36	2	200	Corrosion resistance, weldability	Welded ducts
Steel								
4000-series	0.283	29.0	125–280	109–244	40–100	500–900	Strength	Landing gear, high-strength parts
9Ni-4Co-.3C	0.284	28.5	220	209	80	900	Combined strength and toughness	Fracture-critical parts and fittings
CRES								
300-series	0.286	26.0–29.0	70–175	23–83	2	700–1000	Corrosion resistance, weldability	Sheet metal, welded parts, castings
PH-series	0.279–0.283	28.3–28.5	125–200	95–200	75	600–800	Corrosion resistance, strength, and toughness	Fittings
Titanium								
Annealed or cold-worked CP, 6-4	0.160–0.163	15.0–16.0	80–135	70–130	≤ 70	500–750	Weldability, corrosion resistance, lightweight	Sheet metal parts, welded parts, hydraulic tubes, and structural parts
Heat-treated 6-4, 10-2-3	0.160–0.174	15.0–16.0	130–173	126–168	40	500–750	Strength, corrosion resistance, lightweight	Landing gear fittings, structural parts, fasteners, and standard parts
Nickel								
Annealed 625	0.305	29.8	120	53	2	1800	Temperature resistance, weldability	Welded ducts

<sup>1</sup> Reference only. Not to be used for design.

<sup>2</sup> Composite density depends on volume fraction and density of constituents.

<sup>3</sup> Composite design strengths and modulus depend on constituent property values, fiber volume fraction, and fiber orientation, tailored to directional load requirements, and must account for the notch-sensitivity of most composite materials.

Most material choices involve engineering judgment in seeking the optimum combination of material properties for particular applications and requirements. For example, designers must consider the trade between strength and toughness when selecting alloys and their heat treatments. For minimum weight, high specific strength is desired. For damage tolerance, high toughness is needed. In general, however, as strength increases, toughness decreases. The best engineering solution is a material that is strong enough and tough enough, and provides the minimum weight design at lowest cost. Depending on the operating environment and the system and design requirements, one property or another may be critical, and the material choice is made accordingly. [Table 175.3](#) shows structural material weight percentages for several current airplanes.

**Table 175.3** Structural Material Weight Percentage for Some Current Airplanes

Material	Airplane and Manufacturer			
	McDonnell Douglas AV-8B	McDonnell Douglas F/A-18	Boeing 747	Boeing 777
Aluminum	38	29	70	59
Steel	12	14	11	13
Titanium	8	15	4	6
Composites	26	22	3	9
Other	16	20	12	13

Testing plays an important role in design evolution. It is very important that the correct tests be done in the correct manner to avoid costly mistakes that can result when improper materials are chosen for an application. The scale of testing to interrogate materials and structural capabilities ranges from small, relatively inexpensive material coupon tests to large, relatively expensive tests of full-scale articles, with intermediate levels of element, subcomponent, and component tests. The goal of a successful materials test program is to obtain the required data in the least expensive way that will ensure that, while in service, the materials will perform in the way intended, and will neither experience premature failure nor require excessive maintenance. Testing of structures containing both composite and metallic materials presents special challenges because of differing critical design conditions and strain responses to loading.

The American Society for Testing and Materials (ASTM) has developed standard test specimen geometries and test techniques for many aerospace (as well as other) materials. It is desirable to use standard test methods wherever possible. Underlying principles of materials testing include assurances that test techniques do not influence test results, that test data are reproducible, and that the tests are in fact providing reliable information that can be used in making sound engineering design decisions.

## 175.3 Nonstructural Materials

As with structural materials, nonstructural aerospace materials must satisfy high standards for performance and reliability. All are qualified through analysis and test before commitment to production. For example, interior materials for commercial aircraft must satisfy federal requirements for low smoke and toxic emission in a fire. In addition, these materials must be durable, decorative, and cleanable. Windshields must meet standards for birdstrikes. Compliance is demonstrated by analysis and test. Wiring and electronic components must meet standards for reliability in the service environment. Paints must be environmentally friendly and strippable to enable vehicle refurbishment without damage to the basic structure. Sealants must have good work-life properties for application, and must perform in the service environment for the life of the system.

## 175.4 The Future

---

Aerospace systems of the future must be more affordable. Potential materials and process contributions to this thrust include lower costs for raw materials, fabrication, assembly, and maintenance. Innovative design concepts and materials and process improvements will help achieve the goal of more affordable systems.

There has been significant progress in the understanding of fundamental materials behavior, enabling improved prediction of materials performance in service. The understanding is not complete, however. Research must continue to ensure higher standards of excellence in aerospace materials.

Increased concern for the environment has had a significant influence on how materials are produced, processed, and disposed. Some materials are being replaced by more environmentally friendly materials that meet all performance requirements. The downward trend of toxic chemical releases into the environment is expected to continue.

### Defining Terms

**Advanced composite material:** Stiff, strong, and lightweight material consisting of a matrix, such as epoxy, reinforced by strong, stiff filaments, such as carbon.

**Control limits:** Limits of critical process parameters for the process to be considered in control; the boundaries of acceptable performance.

**Material allowable:** A statistically derived material mechanical property value, based on coupon tests, that is used in developing design allowables. An A-basis material allowable is a value that is equaled or exceeded by 99% of the population of values with a confidence of 95%. A B-basis material allowable is a value that is equaled or exceeded by 90% of the population of values with a confidence of 95%.

### Jan C. Monk

*National Aeronautics and Space Administration*

Rocket propulsion is an application of Newton's first, second, and third laws of motion. Newton's first law of motion states that a particle not subjected to external forces remains at rest or moves with constant velocity in a straight line. A rocket lifting off the launch pad goes from a state of rest to a state of motion. Newton's second law of motion states that force equals mass times acceleration. Force in the equation is the rocket thrust, where mass is the amount of rocket fuel being burned and converted into gas, which expands and then escapes from the rocket. As the gas exits the combustion chamber through a nozzle, it picks up speed. Newton's third law of motion states for every action, there is an equal and opposite reaction. With rockets, the action is the expelling of gas out of the engine; the reaction is the force or thrust of the rocket in the opposite direction.

## 176.1 Performance Characteristics

---

In the process of producing thrust, rocket engines generate more power per unit weight than any other engine. To enable a rocket to climb into low-earth orbit, it is necessary to achieve velocities in excess of 28 000 km per hour. Escape velocity is a speed of about 40 250 km per hour. To achieve these velocities, the rocket engine must burn a large amount of fuel and push the resulting gas out of the engine as rapidly as possible. Containing and controlling this power is the basic challenge in the development of these devices. For example, the power density produced by liquid hydrogen (LH<sub>2</sub>) turbomachinery utilized by the space shuttle main engine (SSME) is approximately 83 horsepower per pound of turbopump weight.

Rocket propulsion system design solutions are quite varied: thrust levels from ounces to millions of pounds force; liquid and solid **propellants**; and liquid systems with pressures that are maintained by turbopumps or pressurized tanks. Liquid system applications vary from small

pressure-fed, storable monopropellant thrusters for keeping satellites stationary, to large turbopump-fed, cryogenic bipropellant engines for boost propulsion. **Combustion chamber** pressures vary from a few pounds per square inch (psi) to several thousand psi. Generally, liquid propulsion systems consist of a propellant feed system, an **injector**, a combustion chamber, and a nozzle. The propellant feed system includes ducting and valves for controlling flows and, in the case of pump-fed systems, turbomachinery that draws propellants from lightweight propellant tanks and increases the pressure to the level necessary to support the desired combustion chamber pressure.

The ideal rocket propulsion equation is

$$\Delta V_{\text{ideal}} = g_0 I_{\text{sp}} \ln \frac{M_0}{M_1} \quad (176.1)$$

where  $\Delta V_{\text{ideal}}$  is the ideal delta velocity imparted on a vehicle,  $g_0$  is the gravitational constant,  $I_{\text{sp}}$  is the propulsion system's specific impulse,  $M_0$  is the initial mass of the vehicle, and  $M_1$  is the final or burnout mass of the vehicle. This equation provides two important performance parameters: specific impulse, which is a measure of propulsion system efficiency expressed in seconds, and vehicle burnout mass, which includes all structures (tankage, thrust structure, etc.), residual propellants, engine systems, feed systems, pressurization systems, auxiliary systems, electronic systems, upper stages, payload supporting structures, and the payload itself.

One of the more important internal rocket engine parameters is characteristic exhaust velocity, commonly referred to as C-star ( $C^*$ ), which relates combustion chamber pressure, chamber throat area, and propellant flow rate. Theoretical characteristic exhaust velocity  $C^*$  is computed as follows:

$$C^* = \frac{P_{ns} A_t g_0}{\dot{w}_{tc}} \quad (176.2)$$

where  $P_{ns}$  is **nozzle** stagnation pressure in psi,  $A_t$  is throat area in square inches, and  $\dot{w}_{tc}$  is chamber propellant mass flow rate in pounds-mass per second. A number of losses will reduce the actual  $C^*$  realized. These losses are generally a function of injector design and are related to mixture ratio maldistribution, mixing, etc. The actual  $C^*$  realized by a given design is,

$$C_{\text{act}}^* = \eta_{c^*} C^* \quad (176.3)$$

where  $\eta_{c^*}$  is  $C^*$  efficiency, typically between 0.80 and 0.99.

Another useful parameter is thrust coefficient, which relates thrust  $F$ , chamber pressure, and throat area as follows:

$$F = C_F P_{ns} A_t \quad (176.4)$$

where  $C_F$  is the thrust coefficient,  $P_{ns}$  is nozzle stagnation pressure, and  $A_t$  is throat area. Once again, additional parameters must be added to reflect actual values. This yields the following:

$$F = \eta_{CF} C_F P_{ns} A_t - P_a A_e \quad (176.5)$$

where  $\eta_{CF}$  is thrust coefficient efficiency, typically between 0.90 and 0.97,  $P_a$  is local atmospheric pressure in psi, and  $A_e$  is exit area in square inches. This equation yields thrust at any point between **sea level** and **vacuum** conditions.

Specific impulse  $I_{sp}$  is an overall efficiency term and is defined as

$$I_{sp} = \frac{F}{\dot{w}_t} \quad (176.6)$$

where  $F$  is thrust level in pounds-force and  $\dot{w}_t$  is the total mass flow rate in pounds-mass per second. Specific impulse can be computed for the engine or thrust chamber by utilizing either engine thrust and flow rate or thrust chamber thrust and flow rate, as appropriate. Specific impulse can also be computed if  $C^*$  and the thrust coefficient are known. This relationship is expressed as

$$I_{sp} = \frac{C^* C_F}{g_0} \quad (176.7)$$

Again, one must maintain consistency between theoretical values and actual values.

Thrust and specific impulse are commonly calculated at either sea level or vacuum conditions for reference or comparative purposes. Later discussions will refer to sea level thrust ( $F_{sl}$ ), vacuum thrust ( $F_{vac}$ ), sea level specific impulse ( $I_{sp_{sl}}$ ), and vacuum specific impulse ( $I_{sp_{vac}}$ ).

Mixture ratio is the ratio between the oxidizer and fuel flow rates, and is expressed in equation form as

$$MR = \frac{\dot{w}_o}{\dot{w}_F} \quad (176.8)$$

where  $\dot{w}_o$  is oxidizer flow rate in pounds per second and  $\dot{w}_F$  is fuel flow rate in pounds per second. Mixture ratio can be computed for the engine or thrust chamber by utilizing either engine flow rates or thrust chamber flow rates, as appropriate.

Expansion ratio  $\varepsilon$  is a ratio of the thrust chamber nozzle exit area,  $A_e$ , and the thrust chamber throat area,  $A_t$ :

$$\varepsilon = \frac{A_e}{A_t} \quad (176.9)$$

A more complete definition of these and other rocket engine equations, including solid propellant systems, can be found in *Rocket Propulsion Elements* [Sutton, 1992].

## 176.2 Liquid Rocket Engine Cycles

A number of power cycles are available for liquid propellant systems. These include pressure-fed,

expander, gas generator, and staged combustion cycles. Each cycle has advantages and disadvantages; the one selected for a given application is determined after a series of system trade studies. A description of a number of engine systems is given in [Table 176.1](#). A brief description of each of these power cycles follows.

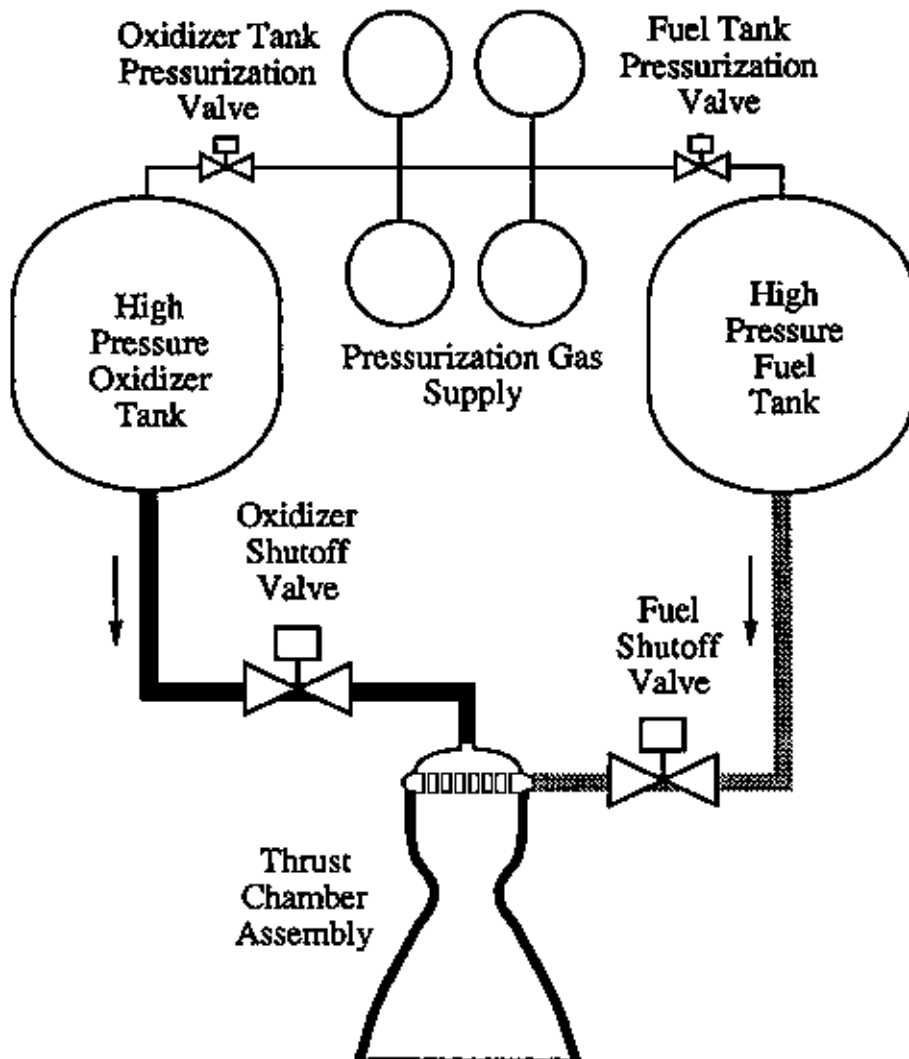

**Table 176.1** Liquid Rocket Engine Characteristics

## Pressure-fed

This system consists of a **thrust chamber assembly**, associated ducting and valves necessary for control, pressurized tankage, and the pressurization system for the tankage. This system is widely utilized for satellite attitude control, orbital transfer, and as auxiliary propulsion for most major launch vehicles. Pressure-fed systems are perhaps the simplest of all propulsion systems, but are performance limited because of the weight penalty associated with increasing chamber pressures. As pressures increase, tank wall thickness and the mass of the gases needed to maintain tank pressures increase. Tank pressures are set by chamber pressure plus pressure losses in the cooling circuit (if any), injector, valves, and ducting. In most pressure-fed applications, combustion chambers are passively cooled (i.e., film-cooled or radiative/**ablative**). The space shuttle utilizes pressure-fed systems for the orbital maneuvering system and the reaction control system. A schematic of a simple pressure-fed system is given in [Fig. 176.1](#).

**Figure 176.1** Pressure-fed propulsion system schematic.

## Expander

This is the simplest of the turbopump-fed systems primarily because the power source for the turbines is the thrust chamber cooling circuit. Only the thrust chamber requires an ignition system. Pump discharge pressures are set by chamber pressure plus pressure losses in the cooling circuit, turbine, injector, valves, and ducting. The combustion chamber is **regeneratively cooled**. In some applications, extensible radiation-cooled nozzle extensions are used to increase area ratio while maintaining a short stowed length. Expander cycles are limited in the combustion chamber pressure that can be attained because the energy available to drive the turbine(s) is obtained from the combustion chamber cooling circuit. For applications that require operation at sea level, this reduces the area ratio that can be achieved without **side loads**. Nozzle flow separation is discussed

later. The RL10 engine is utilized by the Centaur upper stage for the Atlas-Centaur and Titan-Centaur launch vehicles. A schematic of a simple expander system is given in [Fig. 176.2](#) .

**Figure 176.2** Expander engine system schematic.

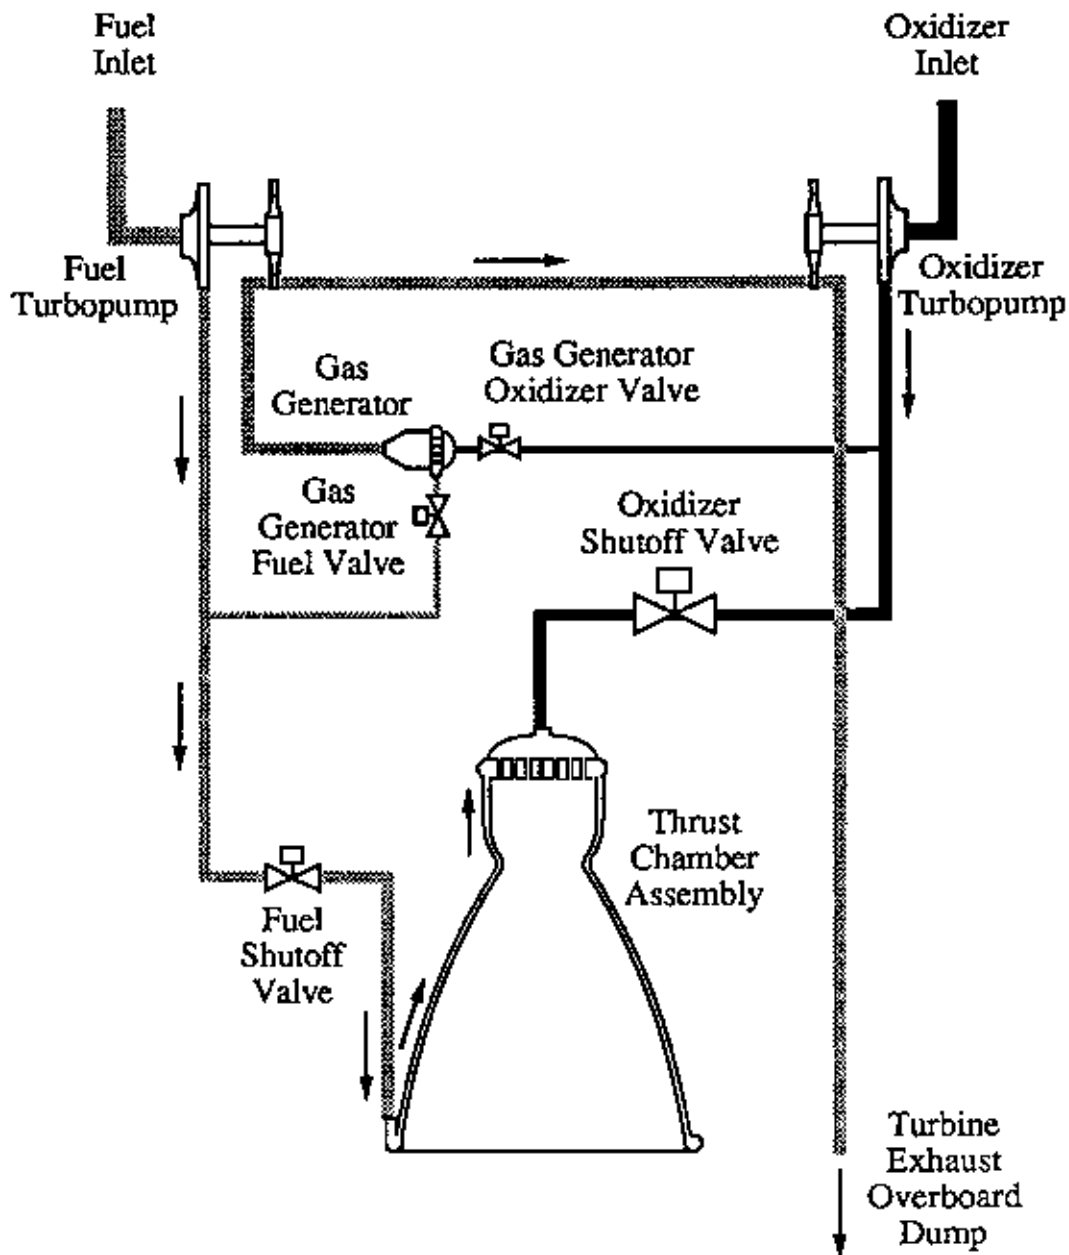

## Gas Generator

This is the most common engine cycle in use today. Turbine power is derived from a separate combustor or gas generator (GG) which utilizes the same propellants as the main system. This hot gas is routed through the turbopump turbines and is dumped overboard. Pump discharge pressures are set by chamber pressure plus pressure losses in the cooling circuit, injector, valves, and ducting. Because the gas generator is parallel to the main chamber, turbine pressure losses do not impact pump discharge pressure in most designs. This highlights one of the disadvantages of this cycle. The gas generator propellants are not used in the main chamber to produce thrust. Some concepts use GG gases for cooling nozzle extensions, but the thrust added is minimal. Gas

generators are operated at relatively low mixture ratios because turbine temperatures must be maintained in the 1000 to 2000 degrees Rankine range. The main combustor mixture ratio is biased higher to offset this parasitic flow. The combination of poor thrust efficiency of the GG gases and main chamber mixture ratio bias results in a specific impulse penalty. The gas generator cycle was utilized on the F-1 and J-2 engines of the Saturn V launch vehicle and is currently in use on the Delta, Atlas, and Titan launch vehicles. A schematic of a simple gas generator system is given in Fig. 176.3.

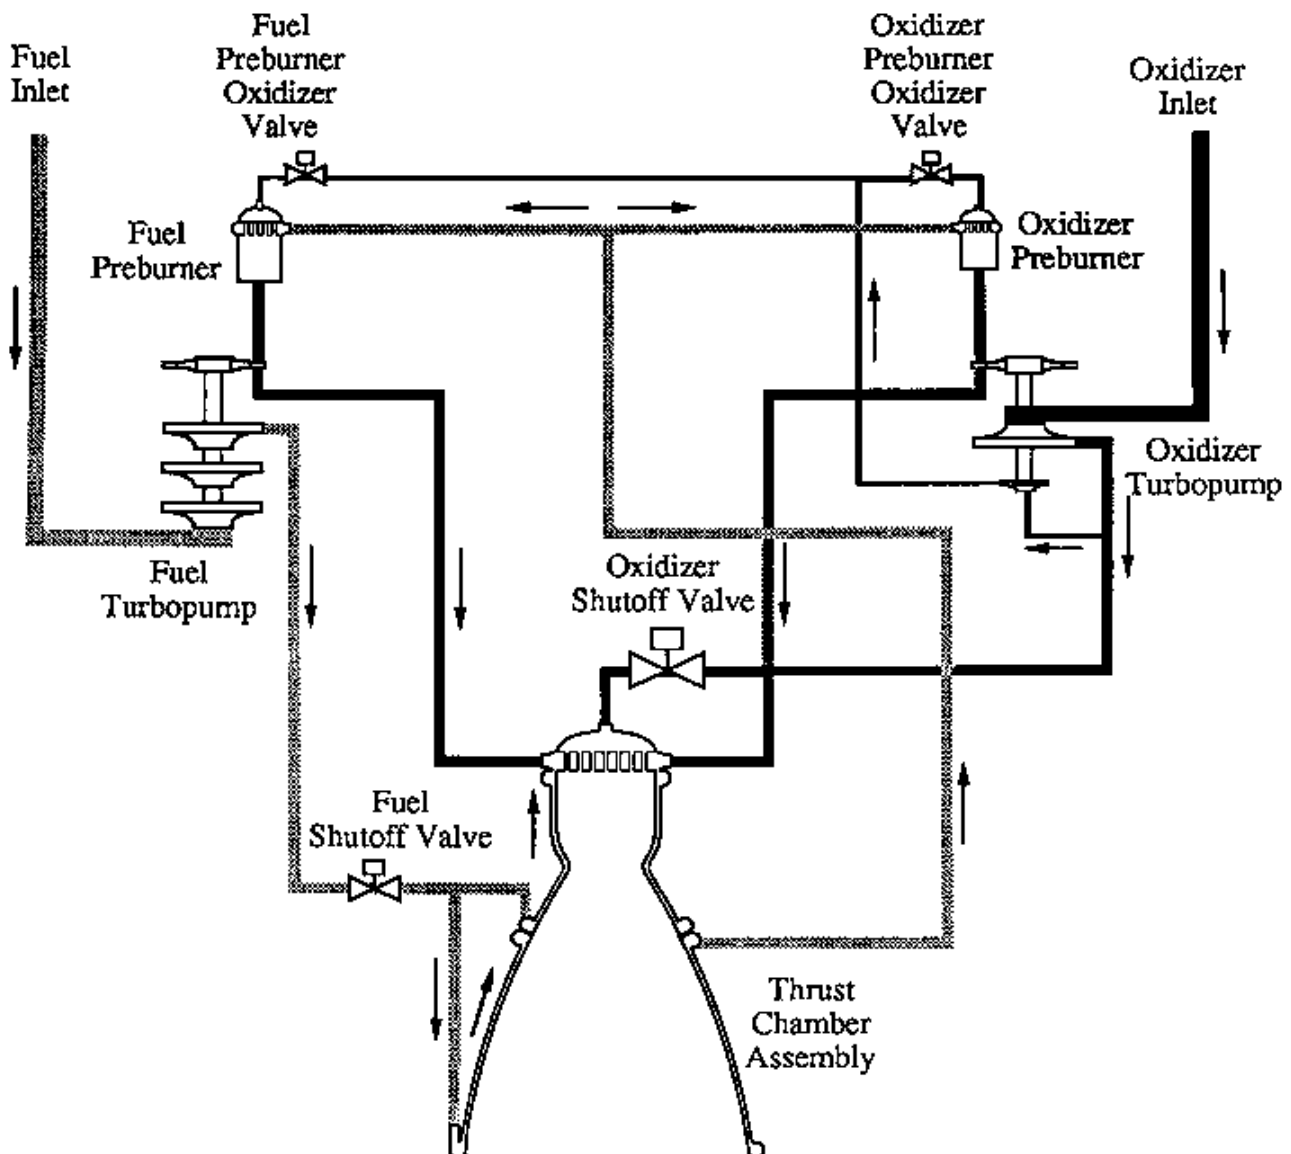

**Figure 176.3** Gas generator engine system schematic.

## Staged Combustion

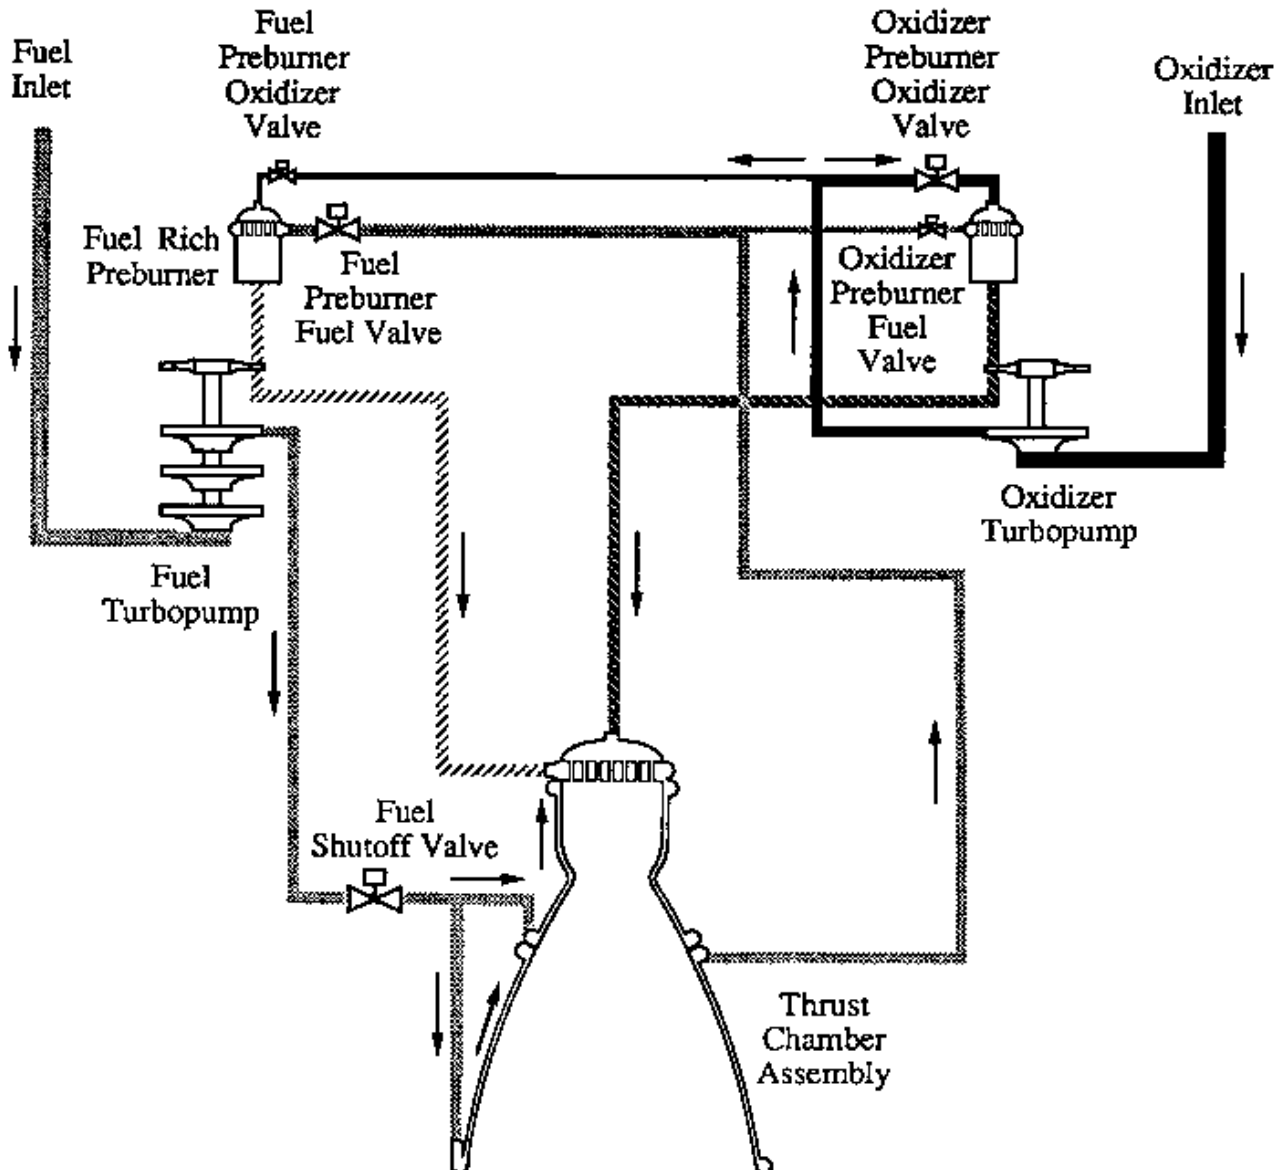

The staged combustion cycle provides the highest performance of conventional chemical rocket engines. Turbine power is derived from a separate combustor or preburner which also utilizes the same propellants as the main system. In bipropellant systems, the hot gas is routed through the turbopump turbines to the main injector where it is mixed with the other propellant and is combusted in the main chamber. Pump discharge pressures are set by chamber pressure plus pressure losses in the cooling circuit, turbine, injector, valves, and ducting. Thrust chambers are regeneratively cooled. Staged combustion cycle engines developed in the U.S. have utilized a fuel-rich preburner. Several rocket engine systems developed in Russia have utilized an oxidizer-rich preburner. In the former case, the fuel-rich hot gases are mixed with oxidizer in the main chamber. In the latter, oxidizer-rich hot gases are mixed with fuel in the main chamber. The staged combustion cycle utilizes all propellants in the main combustion chamber, which provides maximum performance. A schematic of a simple staged combustion system is given in [Fig. 176.4](#).

**Figure 176.4** Staged combustion cycle engine system schematic.

A variant of the staged combustion cycle is the full flow cycle, in which the oxidizer pump turbine is driven with an oxidizer-rich preburner and the fuel pump is driven with a fuel-rich preburner. This cycle offers some simplification in turbomachinery design because of the simplified seal design between the pump end and the turbine end, and a significant reduction in turbine temperatures because all the propellants can be utilized in the turbine drive circuits. This concept is currently under study as a candidate engine system for the next generation launch vehicle. A schematic of a simple full flow staged combustion system is given in Fig. 176.5 .

**Figure 176.5** Full flow staged combustion cycle engine system schematic.

## 176.3 Major Components

### Main Injector

The purpose of the injector is to introduce propellants into the combustion chamber in a controlled manner, to atomize the propellants, and to mix the propellants at the proper mixture ratio in a homogenous manner. Mixture ratio variations across the injector face are one of the most common problems that the designer will encounter, and these maldistributions lead to combustion efficiency losses. In some cases, maldistributions are deliberately introduced. To enhance the durability of combustion chambers, a film of fuel is injected at the outer circumference of the injector. In order to produce a stable combustion process, baffle elements which are cooled with fuel are commonly used. The most common injector concepts are coaxial, showerhead, and impinging. These are illustrated in Fig. 176.6.

**Figure 176.6** Injector concepts.

The coaxial injector consists of a series of concentric tubes into which the oxidizer is introduced through a center tube and the fuel introduced through the annular area formed by a second tube. This type of injector is commonly used in oxygen-hydrogen engines. Impinging and showerhead injectors, which are commonly used in oxygen-kerosene and storable propellant engines, consist of a series of two sets of orifices. One injects the oxidizer, and the other the fuel. The number of orifices, injection velocities, and injection angles are selected to provide consistent atomization and mixing of propellants. Impinging injectors slant the orifices to impinge the two propellant streams against each, enhancing mixing. The design utilized by the conventional impinging injector consists of a series of concentric copper rings containing the injection orifices. The rings alternate between oxidizer and fuel. The outer ring is generally a fuel ring and contains a set of smaller orifices that control film coolant for the combustion chamber. Separate manifolding routes propellants to each set of orifices.

## Thrust Chamber

A number of design solutions have been utilized in thrust chambers, varying from passively cooled ablatives to a number of regeneratively cooled concepts. In some applications, the thrust chamber is composed of two separate components. The upper portion—including the throat region and a portion of the expansion region—is commonly called a combustion chamber. The lower portion—consisting of the remainder of the expansion region—is called a nozzle. Regeneratively cooled thrust chamber designs include brazed tube bundles, copper with milled channels, and steel with milled channels. The bundled tube concept utilizes: steel tubes, pressed to vary the shape necessary for formation of the overall thrust chamber shape; a structural shell in the combustion chamber region with a number of straps spaced along the thrust chamber length for additional strength; and necessary manifolding for inlet and discharge coolant flow. For higher pressure applications (greater than approximately 1800 psia), the heat load produced by the combustion process exceeds the capability of brazed tube designs. For these applications, a copper liner is required in the high heat flux region. This configuration consists of a slotted copper liner, structural jacket, and manifolding. [Figure 176.7](#) illustrates these two thrust chamber concepts.

**Figure 176.7** Two thrust chamber concepts.

#### MANNED MANEUVERING UNIT

Astronaut Bruce McCandless II is a few meters away from the cabin of the earth-orbiting Space Shuttle *Challenger* in this 70 mm photograph taken on February 7, 1984. McCandless is one of the two 41-B mission specialists who participated in this historical extravehicular activity (EVA). This spacewalk represented the first use of a nitrogen-propelled, hand-controlled device called the

Manned Maneuvering Unit (MMU), which allows for much greater mobility than that afforded previous spacewalkers, who had to use restrictive tethers.

The MMU is a self-contained backpack with nitrogen gas propulsion that allows orbiter crews to move outside the payload bay to other parts of the orbiter or to other spacecraft. The MMU latches to the spacesuit (Extravehicular Mobility Unit, EMU) backpack and can be donned and doffed by an astronaut unassisted.

MMU controls follow the layout familiar to spacecraft crews: the left-hand controller governs fore–aft, right–left, and up–down translations, while the right-hand controller handles roll, pitch, and yaw motions. The controllers may be used singly or in combination to give a full range of movement within the operating logic of 729 command combinations, including attitude hold.

Thrust impulses are from 24 dry nitrogen gas thrusters each with 7.56 newtons thrust. Two 25-by-76 centimeter (9.8-by-30 inch) Kevlar filament-wrapped aluminum nitrogen tanks each hold 5.9 kilograms (13 pounds) of nitrogen when fully charged. Two 16.8 volt, 752 watt-hour silver zinc batteries supply MMU electrical power, enough for one six-hour EVA. The nitrogen tanks could be recharged in less than 20 minutes at the payload bay MMU service rack.

Built by Martin Marietta, Denver, CO, the MMU is 1.2 m (49.4 in.) high, 81 cm (32.5 in.) wide, and 1.1 m (44.2 in.) deep with control arms extended. The MMU weighs 136 kg (300 lb) when charged with nitrogen. With a spacesuited crewman and consumables added, on-orbit mass is about 335 kg (740 lb). (Photo courtesy of National Aeronautics and Space Administration.)

## Turbomachinery

The turbomachinery design process of liquid rocket engines is very similar to a normal pump/turbine design, except for two critical areas. The first is the critical need to minimize weight. This is perhaps the greatest difference. As stated earlier, the power density of the space shuttle main engine turbopump is 83 horsepower per pound of turbopump weight. The second difference is the dynamic and steady state environments that rocket engines require. Although a number of turbojet engines operate at turbine temperatures significantly higher than most rocket engines, they attain the steady state operating point in a matter of minutes, not in one to four seconds as do rocket engine turbines. This produces severe thermal strains that tax the ability of materials to sustain. Other environments that provide problems in some materials are oxygen and hydrogen. Particle impact, fretting, and rubbing in an oxygen environment can lead to disastrous fires. Susceptibility of materials to hydrogen embrittlement reduces the variety of materials available for the designer or requires platings to protect materials. Another environment to which rocket engine turbomachinery is susceptible is rotor dynamics, which is considerably more critical than in conventional rotating machinery because of the reduced weight of rocket turbopumps. Structural design considerations, including explanation of the processes utilized in the SSME, can be found in *Structural Design/Margin Assessment* [Ryan, 1993].

## 176.4 System Preliminary Design Process

A number of theoretical thrust chamber performance computer models are readily available that provide the basic performance parameters needed to support a conceptual design. The most common is a Finite Area Combustor Theoretical Rocket Performance Program, commonly referred to as the One-Dimensional Equilibrium (ODE) Program referenced in *Computer Program for Calculation of Complex Chemical Equilibrium Compositions and Applications, Supplement I-Transport Properties* [Gordon et al., 1984]. This model generates performance data for various

propellant combinations as a function of mixture ratios, combustion chamber pressures, and nozzle expansion ratios. A sample set of data for liquid oxygen (LO<sub>2</sub>)/liquid hydrogen propellants is given in Table 176.2.

**Table 176.2** Theoretical Performance of Oxygen-Hydrogen Combustor

The following process outlines a methodology of determining the initial set of overall system requirements for a liquid rocket engine. A preliminary set of top-level engine requirements must be established by the vehicle systems designer for a booster engine. For this exercise, they are as follows:

Propellants: Liquid Oxygen/Liquid Hydrogen

Sea-Level Thrust: 400000 pounds force

Mixture Ratio: 6.0:1.0

In some instances, a minimum specific impulse value is specified. However, in most cases, the design value should be selected as the result of vehicle-engine trade studies, along with engine weight, recurring costs, and nonrecurring costs.

One of the first choices to be made by the engine designer is the value of combustion chamber pressure. This choice is also the result of a series of trades. For this exercise, 2000 psia has been chosen and is a good first approximation for the optimum value when recurring costs are one of the more important parameters. This value will provide good performance, while simplifying turbomachinery to two pump stages with moderate turbine temperatures. An initial assumption needs to be made as to engine cycle. For a booster application, either a gas generator cycle or a staged combustion cycle usually provides optimum performance. For this exercise, the staged combustion cycle is selected. This simplifies the initial set of calculations in that the engine flow rate and thrust chamber flow rate are approximately identical. Table 176.3 provides a typical ODE output for a thrust chamber operating at a chamber pressure of 2000 psia and a mixture ratio of 6.0. The first parameter to select is area ratio. From previous vehicle trade studies, the optimum nozzle exit pressure ( $P_e$ ) for a first stage or booster vehicle is approximately 6.5 psia, the optimum for a single-stage-to-orbit vehicle is approximately 4.0 psia, and the optimum for a parallel burn core stage (booster and core stages ignite at sea level) is 2.5 psia. Standard atmospheric conditions for sea level and various altitudes can be found in *Terrestrial Environment (Climatic) Criteria Guidelines for Use in Aerospace Vehicle Development, 1993 Revision* [Johnson, 1993].

PINF = 2000.0 psia.

O/F = 6.0000.

Another consideration is side loads on the nozzle. For an overexpanded nozzle ( $P_e < P_a$ ), unsymmetrical flow separation results if significant dynamic loads are applied to the nozzle (pressure times surface area forces). These side loads can ultimately destroy a nozzle and, at a minimum, result in significant weight increases. Side loads are computed using both empirical techniques and detailed nozzle fluid flow with computational fluid dynamics techniques. Calculating the locations within the nozzle where flow separation will occur is very difficult and side loads can usually be quantified accurately with test data.

As the application for this exercise is a booster, an exit pressure of approximately 6.5 psia is desired. Using Table 176.3, an expansion ratio of 30 yields an exit pressure of 6.2 psia, which is close enough for a first approximation of the engine characteristics. Using the initial vehicle thrust and mixture ratio requirements, theoretical values of  $C^*$  and  $C_F$  obtained from Table 176.3, and assumed values of  $C^*$  efficiency of 0.99 (readily obtainable with oxygen/hydrogen coaxial tube injectors) and  $C_F$  efficiency of 0.97, various engine parameters can be computed using Eqs. (176.3), (176.5), (176.6), (176.8), and (176.9) and are shown below in order of computation:

$F_{vac}$	400 000 lb
Propellants	Oxygen/hydrogen
MR	6.0

$F_{sl}$	351 846 lbf
$I_{sp_{sl}}$	377.41 s

## 176.5 Conclusion

---

The science of rocketry has enabled some of humankind's greatest achievements, ranging from instantaneous global communications and accurate weather forecasting via geostationary satellites to trips to the moon. NASA's space shuttle is one of the most complex flying machines ever built and is the only partially reusable launch vehicle. While several countries have rockets capable of

carrying a variety of payloads, the U.S. and Russia are the only countries with spacecraft that can transport a crew to and from orbit. France and China have expendable launch vehicles now in use, and Japan is developing another.

The U.S. is on the threshold of a next generation launch system. NASA aerospace engineers and industry experts are exploring new concepts, including the first fully reusable launch vehicle. Developing rockets for 21st century missions promotes enhanced technologies to meet new challenges, including balancing design requirements between operability, performance, weight, and cost. The next generation of spaceship will open new doors to the space frontier.

## Defining Terms

**Ablation:** A passive cooling technique in which heat is carried away from a vital part by absorption into a nonvital part, which may melt or vaporize and then fall away, taking the heat with it.

**Combustion chamber:** A device—which includes a throat region—to mix, burn, and control propellants.

**Injector:** A device to distribute and inject propellants into the combustion chamber.

**Nozzle:** A device used to accelerate the combusted gases.

**Propellant:** Fuel [the chemical(s) the rocket burns] and an oxidizer (oxygen compounds) to ignite the fuel.

**Sea level:** Standard atmospheric conditions at an altitude of zero feet.

**Side loads:** Unsymmetrical loads put on a nozzle because of internal flow separation of overexpanded gases.

**Regeneratively cooled:** A cooling technique in which propellants, usually fuel, are utilized to remove heat from the inner wall of a combustor in a heat exchange process.

**Thrust chamber assembly:** An assembly consisting of the main injector, combustion chamber, and nozzle. Depending upon fabrication techniques, the combustion chamber and nozzle can be separate components or combined into a single component.

**Vacuum:** Conditions where atmospheric pressure can be considered to be 0.0 psia.

The Atmosphere • The Aerodynamic Forces • The Propulsion Subsystems • The Weight Fractions

## 177.2 Level Flight

## 177.3 Climbing Flight

## 177.4 Turning Flight

### Francis Joseph Hale

North Carolina State University

Two major considerations in the performance and design of an aircraft are its range and maneuverability. *Range* deals with how far the aircraft can fly with a given fuel load and given payload with specified flight conditions. *Maneuverability* treats turning rates, rates of climb, and acceleration. A performance analysis starts with a knowledge of the physical characteristics of an aircraft, either actual or hypothetical, and determines how the aircraft will fly under various flight conditions. The converse of the performance analysis is the design of an aircraft to meet a set of operational requirements and constraints. Design, however, is an iterative process, and the first few tries, which yield major aircraft characteristics, may be referred to as conceptual or feasibility designs. The performance analysis and preliminary design processes are often intertwined in a series of iterations and it may be difficult to distinguish between the two.

The flight path and behavior of an aircraft are determined by the interaction between its characteristics and those of the environment in which it is operating—namely, the atmosphere. The aircraft characteristics can be categorized as its physical characteristics, such as shape, mass, volume, and surface area; the characteristics of the propulsion, guidance, and control subsystems; and the structural characteristics, such as loading and temperature limitations and the stiffness (rigidity) of the structure. The environment affects the flight of an aircraft through the surface forces and the field force, the acceleration of gravity, which appears as *weight* and is a function of the mass of the aircraft. The surface forces are the aerodynamic forces (lift, drag, and side force), which are strongly dependent upon the shape and surface area of the aircraft and the properties of the atmosphere. The side force also strongly influences the performance of the propulsion systems.

Aircraft operational units are still principally English and will be given preference over SI units in this article with distance in nautical miles (nmi), airspeed in knots (kt) and feet per second (ft/s), force and weight in pounds (lb), and pressure in lb/ft<sup>2</sup>, where 1 nmi = 1.15 mi = 1.84 km; 1 kt = 1 nmi/h = 1.15 mi/h = 1.84 km/h = 0.51 m/s; 1 ft/s = 0.59 kt; 1 lb = 4.448 N = 0.4535 kg; and 1 lb/ft<sup>2</sup> = 47.87 Pa.

## 177.1 Aircraft Forces and Subsystems

### The Atmosphere

Although the standard atmosphere comprises a number of concentric layers surrounding the earth, only the first two layers of the lower atmosphere are of interest. The *troposphere* starts at sea level and is characterized by a decreasing ambient temperature. At 36 089 ft (11 000 m) above sea level (the *tropopause*), the temperature becomes and remains essentially constant in the *stratosphere* until reaching an altitude of 82 021 ft (25 000 m). In the troposphere, as the atmospheric temperature decreases, so does the local speed of sound  $a$ , thus affecting the **Mach number**. The sonic velocity remains constant in the isothermal stratosphere. Table 177.1 is an abbreviated listing, as a function of the altitude  $h$ , of the two atmospheric ratios of most interest—namely, the *density ratio*  $\sigma$  ( $\rho/\rho_o$ ), where  $\rho$  is the atmospheric density at altitude  $h$  and  $\rho_p$  is the sea level density ( $\rho = \rho_o$ ), and the *sonic ratio*  $a^*$  ( $a/a_o$ ). The standard-day sea level values of  $\rho_o$  and  $a_o$  are given below Table 177.1.

**Table 177.1** Standard Atmosphere Ratios

Altitude (1000 ft)	0	10	20	30	36	40	50	60
Density ratio $\sigma$	1.000	0.738	0.533	0.374	0.297	0.246	0.152	0.094
Sonic ratio $a^*$	1.000	0.965	0.929	0.821	0.867	0.867	0.867	0.867

$$\rho_o = 23.769 \cdot 10^{-4} \text{ lb-s/ft}^2; a_o = 1116 \text{ ft/s}$$

A commonly used exponential approximation for the density ratio  $\sigma$  is

$$\sigma = \rho/\rho_o = \exp(-h/\beta) \quad (177.1)$$

where  $\beta$  is an empirical factor with a value of 23 800 ft (7254 m). Because the atmosphere is assumed to be an ideal gas, variations in the actual temperature and pressure will produce appropriate changes in the actual density. Consequently, on a hot day or with a below-standard barometric pressure, the density will be lower than the standard value for that altitude and the aircraft and propulsion system will perform as though at a higher altitude.

### The Aerodynamic Forces

In coordinated flight, the two principal aerodynamic forces are the *lift*  $L$  and the *drag*  $D$ . The lift is perpendicular to the velocity (*airspeed*) of the aircraft and has the primary function of compensating for the weight of the aircraft. The drag is parallel to the airspeed and resists the motion of the aircraft. The wing is the major source of lift and drag and is designed to maximize the lift while minimizing the drag.

Wing parameters of importance with respect to performance are (1) the wing span  $b$ , the distance from wing tip to wing tip; (2) the average chord  $c_w$ , the distance from the front (leading edge) of the wing to the back (trailing edge); and (3) the wing area  $S$ , the area of one side of the wing to

include the area included by the fuselage. The ratio of the wing span to the average wind chord is the **aspect ratio**  $AR$  of the wing, a measure of the narrowness of the wing. The following relationships are useful:

$$S = bc_w; \quad AR = b/c_w = b^2/S \quad (177.2)$$

The lift and drag forces can be obtained from the following expressions:

$$L = \frac{1}{2}\rho_o\sigma V^2 SC_L = qSC_L; \quad D = \frac{1}{2}\rho_o\sigma V^2 SC_D = qSC_D \quad (177.3)$$

where  $q$  is the dynamic pressure and  $C_L$  and  $C_D$  are the dimensionless lift and drag coefficients.

The **drag polar** is an expression of  $C_D$  as a function of  $C_L$  and is an important performance and design parameter. The parabolic drag polar is an approximation that can be used with many subsonic (and thin-winged) aircraft configurations and is written as

$$C_D = C_{DO} + KC_L^2 \quad \text{where } K = 1/(\pi e AR) \quad (177.4)$$

$C_{DO}$  is the *zero-lift drag coefficient* of the aircraft,  $KC_L^2$  represents the *drag-due-to-lift coefficient*, and  $e$  is the *Oswald span efficiency* (on the order of unity and less). The **lift-to-drag ratio** ( $L/D$ ) or ( $C_L/C_D$ ) represents the aerodynamic efficiency of an aircraft. It has a maximum value that is a design characteristic of the aircraft. This value cannot be exceeded, although the aircraft may, and often does, fly at lower values. The expression for a parabolic drag polar is

$$(L/D)_m = 1/[2(KC_{DO})^{1/2}] \quad (177.5)$$

A large  $(L/D)_m$  calls for low values of  $K$  (high  $AR$  and large  $e$ ) and  $C_{DO}$ . [Figure 177.1](#), a typical plot of the  $(L/D)$  ratio for a specific aircraft and specific parabolic drag polar shows the variation in  $(L/D)$  as  $C_L$  varies. Typical values of  $(L/D)_m$  for several classes of aircraft are: 35 for sailplanes, 18 for Mach 0.8 transports, 7 for supersonic aircraft, and 3 for helicopters.

**Figure 177.1** Typical variation of  $L/D$  with  $C_L$  for a specified drag polar.

## The Propulsion Subsystems

Current aircraft engines are **air breathers** that produce thrust or power, or a combination thereof. The turbojet engine represents a thrust producer, whereas an internal combustion engine in combination with a propeller (a *piston-prop*) represents a power producer. Turbofans, unducted fans, turboprops, and propfans combine the characteristics of both to varying degrees. Turbofans and unducted fans are usually described in turbojet terms and turboprops and propfans in piston-prop terms.

The actual performance and functional relationships of an aircraft engine should be obtained from power plant charts. However, to a first approximation, the *thrust*  $T$  (lb) produced by a turbojet can be considered to be independent of the airspeed and, for a given throttle (percent rpm) setting, to be directly proportional to the atmospheric density, so that

$$T(h) \cong T_o \sigma \quad (177.6)$$

where  $T_o$  is the thrust at sea level. Furthermore, the *fuel consumption rate* (lb/h) is proportional to the thrust, so that

$$dW_f/dt = cT \quad (177.7)$$

where  $c$ , the *thrust specific fuel consumption* (tsfc), has the units of lb/h/lb or h<sup>-1</sup>. Although  $c$  varies somewhat with airspeed and altitude, it may, again to a first approximation, be assumed constant for all altitudes and airspeeds. For current turbine engines, the maximum *thrust-to-engine weight ratio* ( $T/W_e$ )  $\cong$  5–6. Piston-prop engines can be *aspirated* or *turbocharged*, and produce *shaft power* ( $HP$ ), measured in units of horsepower (hp), which is assumed to be independent of the airspeed but to vary with altitude and power setting. The decrease with altitude of the  $HP$  of an aspirated engine is similar to that for the turbojet, but the  $HP$  of a turbocharged engine with a constant power setting remains constant until the *critical altitude* (15–20 000 ft) is reached and then decreases with altitude. The approximations for the density relationships are

$$HP \cong (HP)_0 \sigma \text{ (aspirated)} \quad \text{and} \quad HP \cong (HP)_0 (\sigma/\sigma_{cr}) \text{ (turbocharged)} \quad (177.8)$$

where  $\sigma_{cr}$  is the density ratio at the critical altitude. Figure 177.2 shows the qualitative relationship of the  $HP$  with altitude of the two types of engines. The variation of turbojet thrust is similar to that of the aspirated engine. The propeller converts the shaft horsepower into the *thrust power*  $P$ , which is equal to the product of the thrust and airspeed  $TV$ . The shaft power, thrust power, and thrust are related by the expressions:

$$P = TV = k\eta_p(HP); \quad T = k\eta_p(HP)/V \quad (177.9)$$

where  $\eta_p$  is the propeller efficiency (on the order of 80 to 85% for a well-designed, constant speed propeller) and  $k$  is a conversion factor with a value of 326 when  $V$  is in knots. Notice that for a given horsepower, the thrust power of a piston-prop is independent of the airspeed. However, the available thrust is inversely proportional to  $V$ , decreasing as the airspeed increases, whereas the thrust of a turbojet is constant and the thrust power ( $TV$ ) increases with  $V$ . Because of these differences, propeller and jet aircraft fly differently for best performance. The fuel consumption rate (lb/h) of a piston-prop is proportional to the  $HP$  being delivered, so that

$$dW_f/dt = c^*(HP) = c^*TV/(k\eta_p) \quad (177.10)$$

where  $c^*$ , the *horsepower specific fuel consumption* (hpsfc) with units of lb/h/hp, has the same variations as the tsfc and will also be assumed to be constant. Current piston-prop engines are relatively small (less than 1000 hp) because they are the heaviest of all the engines with  $(HP)_m/W_e \cong 0.5$  hp/lb of engine weight. The specific fuel consumption is an extremely important performance parameter. Some typical values, all expressed as an equivalent tsfc (lb/h/lb), are

Rocket engines	10
Ramjets	3
Turbojets (with afterburner)	2.5

Turbojets	0.9–1.0
High-bypass turbofans	0.6–0.8
Turboprops	0.5–0.6
Piston-props	0.4–0.5

The order of this list indicates the relative airspeed regime of the flight vehicles in which these engines are used. Piston-props are used in aircraft with airspeeds on the order of 220 kt or less; turboprops have higher speeds up to Mach 0.7 or so; turbofan engines for airspeeds up to M 0.85; and so on up the speed ladder with turbojets (and very low-bypass turbofans) in supersonic aircraft, ramjets for M 3.0 and higher, and rocket engines in missiles and space boosters. Furthermore, the piston-prop engine is the least expensive and the heaviest of the engines, and the cost increases and the weight decreases as the list is ascended.

**Figure 177.2** Variation of piston-prop *HP* with altitude, both aspirated and turbocharged.

## The Weight Fractions

*Weight* may well be the most important consideration in the design and performance of an aircraft.

Every extra pound of weight is accompanied by an increase in the wing area and in the thrust and fuel required, all leading to a further increase in the aircraft weight and adversely affecting the performance and costs (both initial and operating) of the aircraft. **Weight fractions** are useful in performance and design analyses and are obtained by expressing the gross (total) weight of the aircraft  $W_o$  as the sum of the weights of the major components and then dividing each weight by the gross weight. Using a simple weight breakdown made up of the *structural weight*  $W_s$ , the *engine weight*  $W_e$ , the *fuel weight*  $W_f$ , and the *payload weight*  $W_{PL}$ , the *gross weight*  $W_o$  of the aircraft is the sum of these component weights. The weight fractions are obtained by dividing through by  $W_o$  to obtain

$$1 = W_s/W_o + W_e/W_o + W_f/W_o + W_{PL}/W_o \quad (177.11)$$

With this breakdown,  $W_s$  includes not only the weight of the structure, but also the weight of everything not included in the other categories. It includes the weight of all the equipment and landing gear, for example, and even the weight of the flight and cabin crews when appropriate. Aircraft manufacturers often lump  $W_s$  and  $W_e$  together into the *operational empty weight* and combine  $W_f$  and  $W_{PL}$  into the *useful load*. In Eq. (177.11), the sum of the individual fractions must always be unity. For a turbojet,  $W_e/W_o = (T_m/W_o)/(T_m/W_e)$ , and, for a piston-prop,  $W_e/W_o = (HP_m/W_o)/(HP_m/W_e)$ . Values of  $T_m/W_o$  are on the order of 0.25–0.35 for large high-subsonic transports and on the order of 0.1 hp/lb of aircraft weight for the  $HP/W_o$  of the typical piston-prop.

Although the determination of  $W_s$  is quite complex, order of magnitude values for  $W_s/W_o$  can be used to give a feel for its size and significance. As  $W_o$  increases,  $W_s/W_o$  decreases because, for example, minimum volume requirements for cabin and cargo space and fixed equipment weights have a higher impact on the structural weight fractions of the smaller aircraft. For large subsonic transports,  $W_s/W_o$  values are on the order of 0.45, but smaller aircraft, such as fighters and general aviation aircraft, can have values in excess of 0.55. Note that the structural weight does not include engine weight.

The **payload ratio** (the payload weight fraction) is of major interest inasmuch as it relates the payload weight to the gross weight of the aircraft. For example,  $W_{PL}/W_o = 0.1$  means that ten pounds of aircraft weight is required for each pound of payload (or excess weight). As  $W_{PL}/W_o$  is equal to unity minus the sum of the other weight fractions, any increase in any of these three either decreases the payload weight fraction, thus increasing  $W_o$  or decreasing the payload, or decreases  $W_f/W_o$ , thus decreasing the range. For example, the increase of  $T_m/W_o$  to convert a **CTOL** aircraft to a **VSTOL** aircraft can dramatically reduce the range and payload, or increase the gross weight.

## 177.2 Level Flight

---

For any aircraft in unaccelerated level flight,

$$L = W; \quad T = D; \quad dX/dt = V \quad (177.12)$$

The weight, however, does not remain constant during flight. As fuel is used, the weight decreases at a rate that is the negative of the fuel consumption rate [Eq. (177.7)], so that for a turbojet  $dW/dt = -cT$ . The *instantaneous range* (mileage), the nmi per lb of fuel, is equal to  $dX/dt$  divided by  $dW/dt$  and, with the relationship from Eq. (177.13) that the required thrust  $T = W/(L/D)$ , can be expressed as

$$dX/dW_f = V/cT = V(L/D)/cW \quad (177.13)$$

The last expression of Eq. (177.13) shows that the best mileage (maximum range per lb of fuel) of an aircraft is obtained when the product of  $V$  and  $(L/D)$ , which are coupled, is maximized, and  $c$  and  $W$  are individually minimized. Because  $W$  decreases along the flight path, the mileage improves with time and distance.

Although the mileage at a particular point or instant of time is of interest, the range for a given amount of fuel and set of flight conditions and the amount of fuel required to fly a specified range (from point 1 to point 2) are of greater interest. With  $c$  assumed constant, integrating the mileage over the cruise flight path while holding  $V$  and  $C_L$  [and thus  $(L/D)$ ] constant, yields the *Breguet range equation* in the form:

$$X = [V(L/D)/c] \ln MR = [V(L/D)/c] \ln[1/(1 - \zeta)] \quad (177.14)$$

where the **mass ratio**  $MR = W_1/W_2$  and the *cruise-fuel weight fraction*  $\zeta = \Delta W_f/W_1 = (MR - 1)/MR$ . In order to keep both  $V$  and  $C_L$  constant along the flight path as fuel is used, the altitude must increase so as to keep  $W/\sigma$  constant [see Eq. (177.15)]. The required flight path angle, however, is sufficiently small ( $< 1$  deg) so that the level flight approximation is still valid. Such flight is known as *cruise-climb*. It gives the maximum range for a given fuel load and, for long flights in a controlled area, can be approximated by a series of constant altitude legs with appropriate altitude increases (*stepped altitude flight*).

The airspeed  $V$  and  $C_L$  [and thus  $(L/D)$ ] are related by expressions from Eq. (177.12) and Eq. (177.3)—namely,

$$V = \sqrt{\frac{2(W/S)}{\rho_o \sigma C_L}}; \quad C_L = \frac{2(W/S)}{\rho_o \sigma V^2} = \frac{(W/S)}{q} \quad (177.15)$$

Equation (177.15) shows that for a given  $C_L$ , a high airspeed  $V$  calls for a high **wing loading**  $(W/S)$  and a small  $\sigma$  (a high altitude) for good range performance. Consequently, turbojet aircraft *must* fly high and fast to achieve their best range performance. Reduced flight times and flight above weather are bonuses. The best-range airspeed (and maximum range) of a particular turbojet is 60% greater at 30 000 ft than at sea level, and 80% higher at 35 000 ft. For long-range subsonic transports,  $W/S$  values are on the order of 115–130 lb/ft<sup>2</sup>. Shorter-range and fighter aircraft have lower values to meet requirements for shorter runway lengths or for greater maneuverability.

For a piston-prop, the relationships of Eq. (177.13) still apply, but now the thrust power  $TV$  is of primary interest and equilibrium requires that the thrust power be equal to the drag power

( $TV = DV$ ). The required thrust power  $P \equiv TV = WV/(L/D)$ . With  $dW/dt = -dW_f/dt = -c^*TV/(k\eta_p)$ , the mileage (nmi/lb) of a piston-prop is

$$dX/dW_f = k\eta_p V/(c^*TV) = k\eta_p(L/D)(c^*W) \quad (177.16)$$

Notice that the mileage of a piston-prop is explicitly independent of the airspeed, which must, however, be that required to achieve the desired  $(L/D)$ . Good mileage still calls for a high  $(L/D)$  and low values of  $c^*$  and  $W$  as for the turbojet. Holding  $C_L$  [and thus  $(L/D)$ ] constant yields the piston-prop version of the *Breguet range equation*:

$$X = [326\eta_p(L/D)/c^*] \ln MR = [326\eta_p(L/D)/c^*][\ln 1/(1 - \zeta)] \quad (177.17)$$

with  $V$  in kt. Although the range is explicitly independent of  $V$ ,  $V$  must have the value appropriate to the cruise  $(L/D)$ . Increasing  $V$  by increasing the altitude or  $W/S$  will not increase the range but will decrease the flight time (and increase the power required). Although the maximum range occurs when  $(L/D)$  is at its maximum value, the associated airspeed, especially with an aspirated engine, is usually much lower than the maximum airspeed of the aircraft and the required power for cruise is below the best operating point for the engine. Consequently, cruise of a piston-prop is customarily at 75% of the maximum power available to reduce flight time and favor the engine. With respect to other power plants, whereas a turbojet is a single-flow engine that produces only jet thrust, a *turbopan* is a multistage engine that uses a turbine to drive a multibladed ducted fan that produces thrust power in addition to jet thrust. It has characteristics of both turbojet and propeller aircraft, and its performance (and specific fuel consumption) lies in the region between the two but closer to the turbojet. The turbojet range equation is used.

A *turboprop*, on the other hand, is primarily a power producer, with little or no jet thrust, that uses the piston-prop equations and is replacing the piston-prop because it is lighter and capable of higher speeds. It has a lower  $C_{DO}$ , but a higher sfc, than the piston-prop. *Derating* a turboprop results in an altitude variation of the power that resembles that of a turbocharged piston-prop. The maximum airspeed of a turboprop with a conventional propeller is limited by the drop in  $\eta_p$  at the higher airspeeds. The *propfan* uses a double row of multibladed, variable camber propellers to increase the operating airspeed. The unducted fan (UDF) with an ultrahigh bypass ratio is still driven directly from the turbine, but resembles the propfan in appearance and approaches its performance. The *absolute ceiling* of an aircraft occurs when the maximum available thrust of a turbojet is equal to the required thrust,  $T_m = W/(L/D)_m$ , or when the maximum available power of a piston-prop is equal to the required power,  $(HP)_m = WV/[k\eta_p(L/D)_m]$ . At the ceiling, the rate of climb is zero and the aircraft cannot turn without losing altitude.

## 177.3 Climbing Flight

The steady-state climbing flight equations are

$$T - D - W \sin \gamma = 0; \quad L - W \cos \gamma = 0; \quad R/C = dh/dt = V \sin \gamma \quad (177.18)$$

where  $\gamma$ , the *climb (flight path) angle*, is the angle between the horizon and the airspeed vector. The two climb equations of interest are

$$\begin{aligned} \sin \gamma &= (T - D)/W = (T/W) - [\cos \gamma/(L/D)]; \\ R/C &= V \sin \gamma = (TV - DV)/W \end{aligned} \quad (177.19)$$

The first expression in Eq. (177.19) shows that  $\gamma$  is determined by the *excess thrust* (the thrust not needed to overcome the drag) per unit weight, whereas the  $R/C$  is determined by the amount of *excess power* per unit weight. The two climb programs of special interest are *steepest climb*,  $\gamma_m$ , and *fastest climb*,  $(R/C)_m$ . Both have their largest values at sea level, where the excess thrust and power are at a maximum, and both decrease with altitude until  $\gamma$  and  $R/C$  both go to zero at the absolute ceiling. Using the expressions of Eq. (177.19), the climb performance can be obtained either graphically (as sketched in Fig. 177.3 for a turbojet) for various altitudes, weights, power settings, and velocities, or by analytic methods.

**Figure 177.3** Climb relationships for a typical turbojet: (a) climb angle  $\gamma$ ; (b) rate of climb  $R/C$ .

Climb angles for conventional aircraft are not large, as can be seen by dropping the drag term in Eq. (177.20) to obtain the inequality that  $\sin \gamma_m < (T_m/W)$ , which shows that the maximum climb angle for a high-performance turbojet transport, with  $T_m/W = 0.33$ , will be less than  $19^\circ$ . Obviously,  $\gamma$  for  $(R/C)_m$  will be less. As expected, the higher the available thrust for a turbojet and the higher the available power for a piston-prop, the better the climb performance is. In general, the turbojet outclimbs the piston-prop and the climb airspeeds are higher.

## 177.4 Turning Flight

One aspect of maneuverability is the ability to turn. The equations governing steady state turns in the horizontal plane are

$$T = D; \quad L = W / \cos \phi; \quad \dot{\chi} = \frac{g \tan \phi}{V} \quad (177.20)$$

where  $\phi$  is the *bank angle* (deg),  $\dot{\chi}$  is the *turning rate* (rad/s),  $V$  is the airspeed (ft/s), and  $g$  is the acceleration of gravity ( $32.2 \text{ ft/s}^2$ ). The *load factor* is defined as  $n = L/W$  ( $g$ 's). From Eq. (177.20) and Eq. (177.3),

$$\begin{aligned} n &= \frac{L}{W} = \frac{1}{\cos \phi} = \left( \frac{T}{W} \right) (L/D); \\ V &= \sqrt{\frac{2n(W/S)}{\rho_o \sigma C_L}} = \sqrt{\frac{2(W/S)}{\rho_o \sigma C_L \cos \phi}} \end{aligned} \quad (177.21)$$

When  $n > 1 g$ , as in a turn, the airspeed is less than that for wings level flight with the same power setting and the stall speed also decreases. It can be shown that the best turning performance (tightest turn and fastest turn) for both types of aircraft occurs at low speed (on the edge of a stall) and at low altitude while using maximum thrust or power.

### Defining Terms

**Air breathers:** Engines that obtain oxygen from the atmosphere.

**Aspect ratio:** Wingspan divided by the average chord length.

**CTOL:** Conventional (horizontal) takeoff and landing aircraft.

**Drag polar:** Drag coefficient–lift coefficient relationship.

**Lift-to-drag ratio ( $L/D$ ):** Aerodynamic efficiency of an aircraft.

**Mach number:** Airspeed divided by local sonic velocity.

**Mass ratio  $MR$ :** Aircraft weight at start of cruise divided by aircraft weight at end of cruise.

**Payload ratio:** Payload weight divided by gross weight of an aircraft.

**V/STOL:** Aircraft capable of both vertical and short takeoffs and landings.

**Weight fraction:** Component weight divided by aircraft weight.

**Wing loading (W/S):** Aircraft weight divided by wing area (lb/ft<sup>2</sup>).

## 178.5 Spacecraft/Mission Design Process

### Wallace T. Fowler

*University of Texas, Austin*

The design of a spacecraft and the design of its mission are closely related parts of the same iterative process. The mission concept usually comes first, but new missions for existing spacecraft designs have also been developed. The key to any successful design is the development of a good set of requirements. In any case, the mission concept is often changed by design factors, and the spacecraft design is driven by mission requirements. Effort spent in defining and refining requirements is crucial to good design.

The design process starts with either mission concept or spacecraft and arrives at a complete design. However, every design process is unique, and no design is optimal. Factors will always arise that do not seem to fit. When this happens, the mission requirements or the design process should be modified to accommodate or eliminate the unique factors.

The match between spacecraft and mission is determined by a number of factors. The two most important preliminary design factors are the mass of the mission payload and the amount of velocity change,  $\Delta V$ , that must be provided to the payload to carry out the mission. These two factors dictate much of the mission and spacecraft design, being the primary drivers for the mass of the booster assembly. Other primary design factors are the duration of the mission and the destination to which the payload is being sent. A two-day mission on which the spacecraft stays near the earth will require a very different hardware/mission plan combination than will a multiyear mission to an outer planet. If a spacecraft is manned, its design and mission planning are greatly complicated. Factors of safety that are acceptable for unmanned flight are unacceptable for manned flight. Life support and safety equipment, as well as backups for such systems, dominate the design. One factor that should not be ignored during the design of a spacecraft/mission

combination is operations. A detailed operations plan is as important to a successful space mission as is good hardware and a good mission plan. Inclusion of operations planning in the initial spacecraft and mission design process, including planning for contingencies, has the potential for lowering mission costs, increasing the chances of mission success, and lowering the potential for problems caused by unforeseen operator/hardware interactions.

## 178.1 Spacecraft Environments

---

Every spacecraft must be able to survive in several environments. All those built on earth must be able to survive the earth's atmosphere or be protected from it. The earth's standard atmosphere is described in **Chapter 177**, and atmosphere models for other planets are available in NASA literature. The launch environment, characterized by vibration, noise, g-loads, aerodynamic loads, transition from air to vacuum, and so on, is a major test for spacecraft. The space environment presents another set of problems for the designer. Hard vacuum, radiation, and temperature extremes are common to all missions. Spacecraft that fly through or beyond the Van Allen radiation belts experience more severe radiation hazards than those that stay inside the Van Allen belts. For manned spacecraft, extended flight beyond the protection of the Van Allen belts implies special crew radiation shielding. Orbital debris is also a hazard that must be considered.

Vehicles that reenter the earth's atmosphere or enter the atmosphere of another planet must contend with entry aerodynamics and the accompanying loads and heating. For landers, abrasive dust can be a problem. Finally, if a spacecraft has a crew, its internal environment must support life while its structure protects the habitable volume. Good discussions of the role of environment in spacecraft design can be found in Fortescue and Stark [1992] and Griffin and French [1991].

## 178.2 Fundamental Principles

---

The primary factor linking the spacecraft and the mission scenario is linear momentum change, and this is the key driver in overall sizing of the spacecraft and its booster system. Except for missions dominated by attitude control requirements, the mission scenario that requires the lowest total linear momentum change will be the most efficient in terms of propellant. Thus, in designing mission and spacecraft, it is important to (1) explore many mission scenarios to ensure that the total momentum change required is as low as possible; (2) use staging to discard unneeded mass and reduce the propellant required during each mission phase; (3) employ engine/propellant combinations that produce large momentum changes with relatively small amounts of propellant (i.e., propellants with high exhaust velocities relative to the vehicle); (4) keep all spacecraft component masses as small as possible; and (5) use unmanned spacecraft whenever possible to keep vehicle masses small. It is also important to use space-qualified hardware when available (and appropriate) to reduce cost and risk.

The ability of a propulsion system to impart momentum changes to a spacecraft is the velocity of the exhaust with respect to the spacecraft. The key equation is

$$c = I_{sp} g \quad (178.1)$$

where  $c$  is exhaust velocity relative to the vehicle,  $I_{sp}$  is specific impulse, and  $g$  is the acceleration of gravity at the surface of the earth.  $c$  is in m/s (ft/s),  $g$  is in m/s<sup>2</sup> (ft/s<sup>2</sup>), and  $I_{sp}$  is in units of seconds. [Note: the value used for  $g$  in Eq. (178.1) does not change when the spacecraft is in a non-earth gravity field].

Propellant combinations (fuel and oxidizer) are often listed in propulsion references with a corresponding  $I_{sp}$  value. These values imply an appropriate engine in which to combine the propellants efficiently. In spacecraft design studies, trade-offs between propellant storability and  $I_{sp}$  are common.  $I_{sp}$  values for most large solid rockets are just under 300 seconds. The  $I_{sp}$  value for the space shuttle main engines (liquid oxygen–liquid hydrogen) is more than 400 seconds.

A second basic equation, which relates the mass of the spacecraft assembly at the  $i$ th stage in the mission (the total mass to be propelled at that point in the mission) to propellant mass that produces the velocity change, is

$$\Delta V_i = c_i \ln(m_{oi}/m_{fi}) \quad (178.2)$$

where  $\Delta V_i$  is the velocity increment provided to the spacecraft assembly by the propellant in the  $i$ th stage,  $c_i$  is the exhaust velocity of the propulsion system in the  $i$ th stage relative to the spacecraft assembly,  $m_{oi}$  is the mass of the spacecraft assembly prior to burning the propellant in the  $i$ th stage, and  $m_{fi}$  is the mass of the spacecraft assembly after the  $i$ th stage propellant is expended. The mass of the propellant burned in the  $i$ th stage is the difference between  $m_{oi}$  and  $m_{fi}$ .

Sequential staging is a very important concept. Mass that is no longer needed should be discarded as soon as is practical in order to avoid using propellant to change the momentum of useless mass. The following equation shows the total  $\Delta V$  for a two-stage vehicle.

$$\Delta V = c_1 \ln(m_{o1}/m_{f1}) + c_2 \ln(m_{o2}/m_{f2}) \quad (178.3)$$

When staging occurs, excess hardware (tanks, engines, pumps, structure) is dropped after a stage burns out and before the next stage begins its burn. Thus,  $m_{f1}$  will be larger than  $m_{o2}$ . This difference is one of the most important factors in space vehicle design and performance. A good discussion of staging can be found beginning on page 603 of Wertz and Larson [1991].

Equation (178.2) does not apply directly when the two different types of engines with different  $I_{sp}$  values are being used simultaneously. The space shuttle first stage (with solid rocket boosters and main engines burning simultaneously) and the Delta booster (with strap-on solid rockets around a liquid rocket core vehicle) are examples of this. A simple modification of Eq. (178.2) applies, however. This equation looks like Eq. (178.2) but has a significant difference in the definition of the exhaust velocity. For such vehicle mission stages,

$$\Delta V = c^* \ln(m_o/m_f) \quad (178.4)$$

where  $c^*$  is a weighted combination of the exhaust velocities of the two types of engines being used. Specifically,

$$c^* = f_1^* c_1 + f_2^* c_2 \quad (178.5)$$

where  $c_1$  and  $c_2$  are the exhaust velocities for the two engine types being used, and  $f_1$  and  $f_2$  are the respective mass flow rate fractions for the two engine types (note that  $f_1 + f_2 = 1$ ). Equations (178.4) and (178.5) allow characteristic  $\Delta V$  values to be calculated for vehicle stages involving parallel burning of dissimilar engine types.

## 178.3 Spacecraft/Mission Categories

---

### Launch Vehicles

Launch vehicles and launches are a common element/system for almost all spacecraft. The choice of launch vehicle is determined by the mission, the mass to be boosted to orbit, the required  $\Delta V$ , the compatibility between launcher and payload, and the overall cost of the launch (launcher plus launch services). The *International Reference Guide to Space Launch Systems* [Isakowitz, 1991] is an excellent source of information on launchers. A good rule of thumb to keep in mind is that for eastward launches into low earth orbit (LEO) from a latitude of about  $30^\circ$ , between 9300 m/s (30 500 ft/s) and 9450 m/s (31 000 ft/s) total  $\Delta V$  must be supplied by the booster. (This accounts for gravity and drag losses as well as increasing the potential and kinetic energy of the spacecraft.) The time from launch to orbit insertion will depend on the booster acceleration capabilities and constraints, but will generally be less than 8 minutes.

### Sounding Rockets

Sounding rockets are usually small, and their missions are characterized by short mission duration and short times out of the atmosphere of the earth (or another planet). Their objectives are usually scientific, their equipment is powered by batteries, and they usually possess a recovery system for the instrumentation package (or perhaps the entire vehicle). Sounding rocket payloads usually consist of structure, instrumentation, a control system, a power system, communications, and a recovery system. The mass and  $\Delta V$  requirement for a sounding rocket depend primarily on the mass to be boosted, the propellant combination to be used, and the altitude to which the payload is to be sent.

### Earth-Orbiting Spacecraft

There are many varieties of earth-orbiting spacecraft. Examples include the original *Sputnik* and *Explorer* spacecraft, the space shuttle, and communications satellites such as *Intelsat*. There are resource mappers, weather satellites, military satellites, and scientific satellites. There are many active satellites in orbit around the earth today. Useful satellite lifetimes range from a few hours to years. It is likely that the *Lageos* satellite, a passive laser reflector, will be providing useful data for at least 100 years. Typical earth-orbiting spacecraft systems are the structure, power system, thermal management system, communications, sensors, computation/data storage, propulsion, and possibly a deorbit/entry system. Launch dates, orbits, and missions of a wide variety of

earth-orbiting spacecraft have been summarized in compact form in the *TRW Space Log* [Thompson, 1987]. Especially useful are the summary documents in this series.

## Lunar Spacecraft

A special category of earth-orbiting spacecraft meriting separate mention are lunar spacecraft. Such spacecraft must climb out of the earth's gravity well, requiring a  $\Delta V$  of more than 3100 m/s (10 200 ft/s) to reach the moon starting in LEO. Spacecraft that orbit the moon require about 1070 m/s (3500 ft/s) to enter an orbit about the moon and 2070 m/s (6800 ft/s) to land. Special thermal considerations are necessary for vehicles designed to rest on the lunar surface because of the slow rotation rate of the moon (the lunar day and night are 14 earth days each). Lunar spacecraft have the systems typical of earth-orbiting spacecraft, with the possible exception of the deorbit/entry system.

## Interplanetary Spacecraft

Interplanetary spacecraft have much in common with lunar vehicles, but they also have many unique characteristics. Spacecraft targeted to the outer planets have longer mission times and different power supplies than those that remain in the inner solar system. The inner planets (Venus and Mercury) present particular problems for the designer of landers. The atmosphere of Venus is hot, dense, and corrosive. The surface of Mercury, except near the poles, sees wide swings in temperature. A point on the equator of Mercury sees 88 earth days of sunlight followed by 88 earth days of darkness. Obviously, structure, materials, and thermal systems are important for such spacecraft. Injection onto a minimum-energy transfer to Mars requires 3600 m/s (11 800 ft/s). Orbiting Mars will require another 2100 m/s (7000 ft/s).

## Entry Vehicles

Entry vehicles are spacecraft (or spacecraft segments) designed to use aerodynamic lift and drag to slow or turn the spacecraft, leading to an orbital plane change, lowering of an orbit, or a descent into the planetary atmosphere. Aerothermodynamic considerations (both stagnation point temperature and integrated heat load) and deceleration loading dominate the design of such vehicles. Aerodynamic control surfaces are the primary means of trajectory shaping, which in turn controls the heating and deceleration. Survivability is a primary design consideration. An entry vehicle is a special type of hypervelocity vehicle, usually a glider (see **Chapter 177** for additional information).

## Landers

Landers are a special class of spacecraft. Some landers are also entry vehicles and some are not, depending on whether the body on which the landing is to take place has an atmosphere. Landings on targets with atmospheres can involve parachutes, cushions, shock absorbers, and so on. Landings on airless bodies usually involve either rocket braking or braking via penetration of the

surface of the target body.

## **Returning Spacecraft**

Spacecraft that return to the planet of origin are a very special case. Vehicles that fly to earth orbit and then deorbit and land on earth, although complex, are much simpler than vehicles that fly from the earth to a target, land, operate, launch, return to earth, enter the atmosphere, and are recovered. For such vehicles, mass is by far the most important driver for all design decisions, and repeated staging is the primary feature of the overall design. Often the redesign of the staging process can greatly simplify an otherwise complex vehicle and mission (the lunar orbit rendezvous used in the Apollo program is an excellent example).

#### HUBBLE TELESCOPE AND COSTAR REPAIR

Astronaut Thomas D. Akers maneuvers inside the bay of the Hubble Space Telescope (HST) which will house the Corrective Optics Space Telescope Axial Replacement (COSTAR). Akers is assisting astronaut Kathryn C. Thornton with the installation of the 640-pound instrument. Thornton, anchored on the end of the Remote Manipulator System (RMS) arm, is partially visible as she prepares to install the COSTAR. The 70 mm scene is backdropped against the earth and the blackness of space. The two spacewalkers participated in the mission's second and fourth (of five) extravehicular activities (EVAs) designed to service the giant telescope. This photograph was made with a handheld Hasselblad camera from *Endeavour's* cabin. (Photo courtesy of National Aeronautics and Space Administration.)

## 178.4 Spacecraft Subsystems

---

Once the overall mission and spacecraft requirements have been defined, the process of defining requirements for various spacecraft subsystems can begin. The integration of the various subsystems into a harmoniously functioning spacecraft can be very difficult. One way to reduce the difficulties in spacecraft integration is to spend sufficient time and effort *early* in carefully and completely defining the interfaces between the subsystems of the spacecraft. Time spent in defining interfaces will repay itself many times as the design progresses. The following is a brief discussion of the major design considerations of the principal spacecraft subsystems. Chetty [1991], Fortescue and Stark [1992], and Griffin and French [1991] provide excellent discussions of various spacecraft subsystems.

### Structure Subsystem

The structure of the spacecraft holds the components together, provides load paths for launch loads, maneuver loads, and so on, and is usually an integral part of the thermal control system or the electrical system for the spacecraft. Design constraints that the structural subsystem must usually meet include stiffness requirements, placing principal inertia axes in preferred directions, sustaining mission loads, and serving as a ground for all spacecraft electrical equipment. Spacecraft structures can be metallic, composite, or ceramic. Structural mass is generally 5 to 20% of the overall spacecraft launch mass.

### Power Subsystem

The type of power system chosen for a spacecraft is strongly dependent on the mission of the spacecraft and the power demands of the equipment to be carried. Short-duration missions often use batteries. Longer-duration missions that go no farther from the sun than Mars can use photoelectric power (solar cells). Long-duration, low-power missions on which the spacecraft go very far from the sun (e.g., *Voyager*) use radioisotope thermoelectric generators (RTGs). Other potential power sources are solar thermionic systems, chemical dynamic systems, and nuclear power systems.

### Attitude Control Subsystem

Most spacecraft require attitude stabilization to point antennas, properly orient solar arrays, point sensors, and orient thrusters. Attitude control consists of sensing the current attitude of the spacecraft and applying torques to reorient the spacecraft to a desired attitude.

### Three-Axis Stabilization

The most complex and precise spacecraft attitude control is three-axis stabilization accomplished using momentum wheels or reaction wheels. Attitude thrusters are also used for three-axis

stabilization, either as the primary attitude control mechanism or to desaturate the momentum wheels. Three-axis stabilization systems can be fast and accurate. For example, the attitude control system on the Hubble Space Telescope, which uses reaction wheels, can point the optical axis of the telescope to within 0.007 arc seconds of the desired direction.

### **Spin Stabilization**

Spin stabilization is much simpler and less precise than three-axis stabilization. Spin-stabilized spacecraft must be rigid and spinning about the principal axis with the largest mass moment of inertia. The first U.S. orbiting satellite, *Explorer 1* (launched 31 January 1958), provided an early demonstration of the need for spinning spacecraft to be rigid. *Explorer 1* was a long slender cylinder spinning about its long axis. It possessed flexible whip antennas that dissipated energy and caused the spacecraft to tumble within a day of orbit insertion.

### **Dual-Spin Spacecraft**

Some spacecraft have a spinning section and a despun section. Such spacecraft must have systems to maintain the attitude of the despun section and to control the direction of the spin vector. Reactions between the spinning and despun sections are major design and operational considerations.

### **Gravity Gradient Stabilization**

Spacecraft can use the gradient of the gravitational field of a planet to provide restoring torques and maintain the spacecraft in an orientation with the spacecraft's long axis pointing along the local vertical. Spacecraft designed to employ gravity gradient stabilization usually feature mass concentrations at the ends of a long boom that lies along the local vertical. Gravity gradient stabilization works best with near-circular orbits and would not work on even moderately elliptic orbits. A pointing accuracy of about  $1^\circ$  with some wobble is achievable with gravity gradient stabilization of earth satellites.

### **Magnetic Stabilization**

Spacecraft attitudes can be stabilized or changed using torques developed by running currents through coils (torque rods) mounted in the spacecraft if the spacecraft is orbiting a body with a significant magnetic field. The primary difficulty with this type of attitude stabilization system is keeping track of the relative orientations of the spacecraft axes and the magnetic field lines as the spacecraft moves along in its orbit. Magnetic stabilization is slow and coarse.

### **Solar Radiation Stabilization**

The pressure of solar radiation falling on a spacecraft can be used to create torques. Spacecraft that employ solar radiation stabilization are large and lightweight.

## **Telecommunications Subsystem**

The primary function of the telecommunications subsystem is to receive, process, and transmit electronic information. Some satellites (communications, intelligence, and weather satellites) are designed to meet one or more telecommunications mission objective. The telecommunications

subsystem often demands a significant amount of electrical power, and this demand often drives the design of the power system. The spacecraft computer/sequencer can be considered part of the telecommunications system or a separate system. Chetty [1991], Fortescue and Stark [1992], and Griffin and French [1991] provide excellent discussions of spacecraft telecommunications.

## **Propulsion Subsystem**

The spacecraft propulsion subsystem will be considered separately from the launch vehicle and upper stages. The propulsion subsystem is responsible for orbit maintenance, small orbit changes, attitude control system desaturation, and so on. Spacecraft onboard propulsion systems use chemically reacting fuels and oxidizers, monopropellants and catalysts, cold gas, and ion thrusters. Chetty [1991], Fortescue and Stark [1992], and Griffin and French [1991] provide excellent discussions of propulsion systems.

## **Thermal Control Subsystem**

Spacecraft thermal control is of utmost importance. Maintaining appropriate thermal environments for the various spacecraft is essential to proper component function and longevity. The primary problem with thermal management of spacecraft is that all excess heat must ultimately be radiated by the spacecraft. For many unmanned spacecraft, passive thermal control involving coatings, insulators, and radiators is ideal. For other spacecraft, active thermal control is necessary. Active systems can employ heaters, radiators, heat pipes, thermal louvers, and flash evaporators. Significant spacecraft mass reductions can sometimes be made if the excess heat from one component is conducted to another component that would otherwise require active heating.

## **Spacecraft Mechanisms**

Some spacecraft are mechanically passive and have no mechanisms in their designs. However, even these spacecraft require mechanisms to deploy them from their boosters. Mechanically active spacecraft can feature a wide variety of mechanisms. There are deployment systems for booms and antennas, docking mechanisms, robot arms, spin/despin systems, sensor pan and tilt mechanisms, gyroscopes, reaction wheels (also considered as part of the attitude control system), landing legs, and airlocks. The types of mechanisms depend on the mission of the spacecraft.

## **Launch Vehicles**

The launch vehicle, or booster, is an integral part of most spacecraft systems. The *International Reference Guide to Space Launch Systems* [Isakowitz, 1991] covers the capabilities of most currently available launch vehicles in detail. The rotation of the earth has a major effect on launch vehicle performance. The eastward motion of the launch site must be considered when computing the payload that a launch vehicle can place in orbit. The launch azimuth and the latitude-dependent eastward velocity of the launch site can be combined to determine how much velocity assist is provided by earth's rotation. For westward launches (to retrograde orbits), the rotation of the earth

extracts a penalty, requiring additional velocity to be provided by the booster to make up for the eastward velocity of the launch site.

## Upper Stages

Launch vehicles are often combined with upper stages to form a more capable launch vehicle. Commonly used upper stages include the *IUS*, the *Centaur*, and several types of PAM (payload assist modules). Upper stages are also carried aloft in the payload bay of the space shuttle to boost spacecraft to higher orbits. Designers should always consider the option of using an available upper stage if the mission requires more  $\Delta V$  than can be provided by the basic launch vehicle.

## Entry/Landing Subsystems

Entry subsystems can be considered either as a separate set of devices or as parts of other subsystems. The heat shield can be reusable or ablative, and could be considered to be part of the thermal control subsystem. The retrorockets, if any, might be considered to be part of the propulsion system. Parachutes, landing legs, cushions, wings, aerosurfaces, a streamlined shape, and landing gear, when needed, belong solely to the category of entry and landing subsystems.

## Subsystem Integration and Redundancy

The interplay among spacecraft subsystems is great, and their integration into an efficient, smoothly operating, and reliable spacecraft is an immense challenge. Redundant system elements can provide added reliability if the risk of failure must be lowered. However, redundancy increases initial costs and usually increases overall mass. It is often good to avoid physically redundant elements, choosing physically different but functionally redundant elements instead. System elements that are to be functionally duplicated should be identified as early in the design process as possible.

## 178.5 Spacecraft/Mission Design Process

---

The spacecraft/mission design process can be outlined as follows:

1. Beginning with a set of mission goals, develop a set of mission and spacecraft requirements that must be met in order to achieve the goals. An excellent discussion of requirements and how to develop them is found in Wertz and Larson [1991, pp. 55–78]. Mission goals may change during the design process, and when this happens, the requirements must be reevaluated.
2. Before beginning a methodical approach to the design, it is almost always helpful to bring the design team together and conduct a brainstorming session. For those who are unfamiliar with brainstorming, Adams [1986] is recommended. The brainstorming session should be expected to identify several nonorthodox candidate scenarios or components for the mission and spacecraft.
3. Develop a conceptual model for the spacecraft and the mission, identifying major systems

and subsystems, and most important, the interfaces between systems, both within the spacecraft itself and between the spacecraft and its support elements on the ground and in space. A preliminary mission scenario and rough timeline should also be developed at this time. These conceptual elements should be developed from the mission and spacecraft requirements. This step will allow the definition of major systems and subsystems and will identify major interactions between mission events and spacecraft hardware elements. Preliminary indications of pointing requirements, required sensor fields of view,  $\Delta V$  requirements, allowable spacecraft mass, and required and desired component lifetimes should come from these considerations. Brown [1992], Fortescue and Stark [1992], Griffin and French [1991], and Isakowitz [1991] give information appropriate to this topic.

4. The role of heritage in spacecraft design is important. Systems and technologies that have worked well on past spacecraft are often good candidates for new spacecraft with similar missions. Examine the recent past for similar missions, spacecraft with similar requirements, and so on. Although sufficiently detailed systems overviews of recent spacecraft are often difficult to obtain, the effort necessary to obtain them is almost always worth it. However, be careful to avoid early adoption of a candidate system from earlier spacecraft to avoid being locked into a system that only marginally meets or does not meet design requirements.
5. Once the first four steps have been taken (some more than once), the design team should develop preliminary spacecraft design candidates (spacecraft/scenario/timeline combinations), concentrating on systems and subsystems and their performance, masses, power requirements, system interactions, thermal input/output, and costs. Several candidate designs should be considered at this stage and their predicted relative characteristics compared. These considerations allow the design team to learn more about the requirements and how best to meet them. It is likely that the design team will recycle through some or all of the design process at this point for one or more of the candidate designs. The possibility of developing a new composite design with the best features of several candidate designs should not be ignored.
6. As candidate designs are refined, the design team should develop criteria for use in choosing among candidate designs. The information on the candidate designs should be organized and presented at a preliminary design review. The feedback from those attending the review is valuable in the identification of strengths and weaknesses of candidate designs.
7. At some point, determined by budget, timeline, technical considerations, and the characteristics of the candidate designs, one design concept must be chosen for development. Once the choice is made, the design team should carry out a complete analysis of the chosen design. This analysis should include a detailed mission scenario and timeline, launch vehicle choice,  $\Delta V$  requirements for every maneuver, hardware choices for every system and subsystem, system interaction analyses, manufacturability considerations, component and overall cost analyses, and failure mode effects analyses. Any remaining system/subsystem hardware choices should be made, and the design should be presented at a critical design review. The feedback from the critical design review will often result in major improvements

in the design. Questions arising at the critical design review will often precipitate another pass through the design process.

## Defining Terms

**Mission scenario:** A sequence of events and times that, in their entirety, meet the objectives of the mission.

**Specific impulse:** The amount of thrust force obtained from a fuel/oxidizer/engine combination when a unit weight of fuel is burned in one second. The units of specific impulse are seconds because the force and weight units cancel.

**Subsystem:** A part of an overall system that can be isolated to some degree. Subsystems interact and cannot actually be isolated, but it is convenient to consider subsystems in sequence rather than all at once.

Hazard Identification Physical Hazards Chemical Hazards Airborne Contaminants Noise Fire Hazards An Engineering Approach to Hazard Control Hazard Analysis and Quantification

#### 180 Regulations and Standards *A. K. Furr*

Engineering Practices Summary

PRIOR TO THE 20TH CENTURY, safety was largely a matter for the individual and, aside from some of the more obvious concepts, was not well understood. Medicine was only beginning to develop into the sophisticated discipline it is today. Few industries had safety programs. There was no significant regulatory protection for individuals, either in the workplace or elsewhere, and the environment was similarly unprotected. During the period prior to World War II, the growth of labor unions stimulated the creation of safety programs and the beginnings of regulatory actions.

After the war, safety and health issues took on increasing importance. A great amount of research was initiated to study safety management techniques, hazard evaluations, hazard amelioration and abatement, health effects of exposure to materials, manufacturing standards, and equipment design. In the early 1970s, safety and health issues received a tremendous boost by the passage of the Occupational Health and Safety Act. The concern of the public about the effects of exposure to hazardous substances in the air, water, and food generated a demand for regulations in these areas. As a result, there are now many regulatory acts which affect virtually every part of an individual's life. Engineers and other professionals must take these regulations into account in all of their activities.

Much of the most recent concern for safety involves an individual's health. Unfortunately, this is the most difficult area in which to establish meaningful regulations. In order to determine a substance's carcinogenic properties, studies must be done which are extremely expensive and may be invalid due to the necessity of using animal models and deriving the effects of normal exposure from data based on high levels of exposure. Statistical epidemiological studies are also difficult except in extreme cases due to problems of establishing statistically significant experimental and control cohorts. Much effort is still required in this area.

Unfortunately, due to the complexity of safety and health issues and regulations, and the feeling on the part of some that compliance is too costly and time consuming, many architects, engineers, and management personnel are not qualified to take advantage of all the information that has been garnered on safety-related factors in their work. Where safety factors and regulations are interpreted by reasonable persons, safety management can be a very cost-effective tool, raising productivity and improving employee morale. Industries which are not concerned about the

environment are finding that they are not welcome in a community. Unfortunately, the "not in my back yard" position has affected other, more responsible firms due to overreaction to these problem situations. It is incumbent on all professionals to work toward re-instilling public confidence that safety and health issues are a principal concern of their professions.

Injuries and illnesses cost American industry an estimated \$115 billion in 1992 [[Occupational Hazards, 1993](#)]. Yet engineered systems are often designed without an extensive evaluation for their potential **hazards**. A glance at multidisciplinary literature in the field of safety and health shows that a large number of tools and techniques are available for hazard identification, analysis, and control. However, little standardization exists for using these techniques across fields such as engineering, physics, chemistry, sociology, psychology, business, and law. Specifically, design engineers do not make extensive use of safety resources commonly recommended by the safety community, nor are they fully familiar with hazard identification and analysis techniques [[Main and Frantz, 1994](#)]. In fact, as the system under study (e.g., product, machine, production cell, shop floor) becomes more complex in terms of hardware, software, and human, environmental, and organizational variables, the need to employ a more comprehensive hazard evaluation and control methodology becomes evident. In addition, the recent developments in environmentally conscious design require a deeper understanding of hazard consequences within and across the product life-cycle span (i.e., design, development, production, operation, deployment, use, and disposal). Therefore, successful safety programs require significant effort and resources on the part of a multidisciplinary team of investigators with support from all levels of management within a safety-cultured organizational structure [[Hansen, 1993](#)].

## 179.1 Hazard Identification

---

It is imperative that engineers become aware of hazard prevention principles early in their education. Also, the principles and techniques outlined in this chapter work best when applied early in the design of systems. The negative impact of hazards (e.g., accidents, diseases) will be far greater (sometimes irreversible) in the later stages of the system design or operations.

One way of classifying the sources of hazards is by the type of dominant (hazardous) energy used in the operation of the system. This energy is normally traced back to the root cause of an injury or illness. In this chapter, the following hazards are considered: physical, chemical, airborne contaminants, noise, and fire. Other hazards are extensively considered in the reference material, and ergonomic hazards are discussed elsewhere in this handbook. The objective of any hazard control program is to control losses from injuries and damages by identifying and controlling the degree of exposure to these sources of energy.

## 179.2 Physical Hazards

---

Physical hazards are usually in the form of kinematic force of lifting or impact by or against an object. More than 50% of compensable work injuries are included in this category.

### Human Impact Injuries

The severity of an injury depends on the velocity of impact, magnitude of deceleration, and body size, orientation, and position. The kinetic energy formula used to describe the impact injury is

$$E_{\text{ft-lb}} = (Wv^2)/2g \quad (179.1)$$

where  $W$  is the weight of an object or part of the body (lb),  $v$  is the velocity (ft/s), and  $g$  is gravity (ft/s<sup>2</sup>). However, if the impacting surface is soft, the kinetic energy for the impact is

$$E_{\text{ft-lb}} = [W(2sA)]/2g \quad (179.2)$$

where  $s$  is the stopping distance (ft), and  $A$  is the deceleration (ft/s<sup>2</sup>). For example, for both of the above cases, the human skull fracture occurs at 50 ft-lb of kinetic energy. Hard hats are expected to prevent the transfer of this energy to the human skull.

### Trip, Slip, and Fall

These injuries comprise 17% of all work-related injuries. Falls are the second largest source of accidental deaths in the U.S. (after motor vehicle accidents). Jobs related to manufacturing, construction, and retail and wholesale activities are the most susceptible to these types of hazards, comprising about 27% of all worker compensation claims in the U.S. These hazards include slipping (on level ground or on a ladder), falling from a higher level to a lower one (or to the ground), falling due to the collapse of a piece of floor or equipment, and failure of a structural support or walkway. Principles of tribology are being used to study the control mechanisms for these accidents. Tribology is the science that deals with the design and analysis of friction, wear,

and lubrication of interacting surfaces in relative motion. The basic measure of concern is the coefficient of friction (COF), which in its simplest form is the horizontal force divided by the vertical force at the point of relative motion. A COF greater than 0.5 appears to provide sufficient traction for normal floor surfaces. However, a number of other conditions make this hazard evaluation difficult: unexpectedness of surface friction change versus human gait progression, foreign objects and debris on a path, walkway depression, raised projections (more than 0.25 in.), change in surface slope, wet surfaces, improper carpeting, insufficient lighting, improper stair and ramp design, improper use of ladders, guardrails and handrails, and human visual deficiencies (color weakness, lack of depth perception and field of view, inattention, and distraction).

## Mechanical Injuries

The U.S. Occupational Safety and Health Act specifically states that one or more methods of machine guarding shall be provided the operator and other employees to protect them from hazards such as those created by point of operation, ingoing nip points, rotating parts, flying chips, and sparks. Other hazards in this category are: cutting by sharp edges, sharp points, poor surface finishes, splinters from wood and metal parts, shearing by one part of a machine moving across a fixed part (e.g., paper cutters or metal shearers), crushing of a skin or a tissue caught between two moving parts (e.g., gears, belts, cables on drums), and straining of a muscle (overexertion) in manual lifting, pushing, twisting, or repetitive motions.

Another important category is the hazard caused by pressure vessels and explosions. These hazards are generally divided into two types—boilers which are used to generate heat and steam, and unfired pressure vessels which are used to contain a process fluid, liquid, or gas without direct contact of burning fuel. The American Society of Mechanical Engineers (ASME) covers all facets of the design, manufacture, installation, and testing of most boilers and process pressure vessels in the Boiler and Pressure Vessel Code (total of 11 volumes). The primary safety considerations relate to the presence of emergency relief devices or valves to reduce the possibility of overpressurization or explosion. Explosions can be classified on the basis of the length-to-diameter ratio ( $L/D$ ) of the container. If the container has an  $L/D$  of approximately one, the rise in pressure is relatively slow and the overpressurization will cause the container to rupture. In containers with a large  $L/D$  ratio, such as gas transfer pipes and long cylinders, the initial flame propagates, creating turbulence in front of it. This turbulence improves mixing and expansion of the flame area and the speed of travel along the vessel, increasing the pressure by as much as 20 times very rapidly. Other types of explosions are caused by airborne dust particles, boiling liquid and expanding vapor, vessels containing nonreactive materials, deflagration of mists, and runaway chemical reactions.

Explosions may have three types of effects on a human body. First, the blast wave effect which carries kinetic energy in a medium (usually air), though decaying with distance, can knock a person down (overpressure of 1.0 lb/in.<sup>2</sup>) or reach a threshold of lung collapse (overpressure of 11 lb/in.<sup>2</sup>). The second type of effect is thermal, usually resulting from the fire. The amount of heat radiated is related to the size of the fireball and its duration of dispersion. The radiant energy is reduced according to the inverse distance-squared law. Most explosive fireballs reach temperatures about 2400°F at their centers. The third effect is the scattering of the material fragments. All three

of these injury effects are multifactorial and they are very difficult to predict.

## 179.3 Chemical Hazards

---

A Union Carbide plant in Bhopal, India, accidentally leaked methyl isocyanate gas from its chemical process. It left over 2500 dead and about 20 000 injured. There are over 3 million chemical compounds, and an estimated 1000 new compounds are introduced every year.

### Hazardous/Toxic Substances

The health hazards of chemicals can be classified into acute or chronic. The acute ones are corrosives, irritants, sensitizers, and toxic and highly **toxic substances**. The chronic ones are carcinogens, liver, kidney and lung toxins, bloodborne pathogens, nervous system damages, and reproductive hazards. For a reference listing of maximum exposures to these substances, refer to the technical committees of the American Conference of Governmental Industrial Hygienists (ACGIH) and American Industrial Hygiene Association (AIHA). Rules and standards related to manufacture, use, and transportation of these chemicals are promulgated and their **compliance** is enforced by governmental agencies such as the Occupational Safety and Health Administration (OSHA), the Environmental Protection Agency (EPA) and the Department of Transportation (DOT).

### Routes of Entry

There are four ways by which toxic substances can enter into the human body and cause external or internal injuries or diseases [Shell and Simmons, 1990].

1. Cutaneous (on or through the skin)
  - a. Corrosives: damage skin by chemical reaction
  - b. Dermatitis: irritants such as strong acids; sensitizers, such as gasoline, naphtha, and some polyethylene compounds
  - c. Absorbed through skin, but affecting other organs
2. Ocular (into or through the eyes)
  - a. Corneal burns due to acids or alkali
  - b. Irritation due to abrasion or chemical reaction
3. Respiratory inhalation (explained later in section 179.4)
4. Ingestion
  - a. Toxic substances may be ingested with contaminated food
  - b. Fingers contaminated with toxic chemicals may be placed in mouth
  - c. Particles in the respiratory system are swallowed with mucus

## Mechanisms of Injury

Toxic agents cause injury by one or a combination of the following mechanisms.

1. Asphyxiants
  - a. Asphyxia refers to a lack of oxygen in the bloodstream or tissues with a high level of carbon dioxide present in the blood or alveoli
  - b. Gas asphyxiants (e.g., carbon dioxide, nitrogen, methane, hydrogen) dilute the air, decreasing oxygen concentration
  - c. Chemical asphyxiants make the hemoglobin incapable of carrying oxygen (carbon monoxide) or keep the body's tissues from utilizing oxygen from the bloodstream (hydrogen cyanide)
2. Irritants which can cause inflammation (heat, swelling, and pain)
  - a. Mild irritants cause hyperemia (capillaries dilate)
  - b. Strong irritants produce blisters
  - c. Respiratory irritants can produce pulmonary edema
  - d. Secondary irritants can be absorbed and act as systemic poisons
3. Systemic poisons
  - a. Poisons may injure the visceral organs, such as the kidney (nephrotoxic agents) or liver (hepatotoxic agents)
  - b. Poisons may injure the bone marrow and spleen, interrupting the production of blood (benzene, naphthalene, lead)
  - c. Poisons may affect the nervous system, causing inflammation of the nerves, neuritis, pain, paralysis, and blindness (methyl alcohol, mercury)
  - d. Poisons may enter the bloodstream and affect organs, bones, and blood throughout the body (usually with prolonged exposure)
4. Anesthetics
  - a. May cause loss of sensation
  - b. May interfere with involuntary muscle actions causing respiratory failure (halogenated hydrocarbons)
5. Neurotoxins
  - a. Neurotics affect the central nervous system
  - b. Depressants cause drowsiness and lethargy (alcohol)
  - c. Stimulants cause hyperactivity
  - d. Hypnotics which are sleep-inducing agents (barbiturates, chloral hydrate)
6. Carcinogens
  - a. Cancers of the skin at points of contact (tar, bitumen)
  - b. Cancers of internal organs and systems have numerous known and suspected causes (labeled as suspected carcinogens)

7. Teratogenic effects. A substance that may cause physical defects in the developing embryo or fetus when a pregnant female is exposed to the substance for a period of time.

## 179.4 Airborne Contaminants

---

The greatest hazard exists when these contaminants have sizes smaller than  $0.5\ \mu\text{m}$  where they can be directly introduced into the bloodstream through alveolar sacs (e.g., zinc oxide, silver iodide). Particles larger than  $0.5\ \mu\text{m}$  are entrapped by the upper respiratory tract of trachea and bronchial tubes (e.g., insecticide dust, cement and foundry dust, sulfuric acid mist). There are two main forms of airborne contaminants [Brauer, 1990]—particulates (dusts, fumes, smoke, aerosols, and mists), and gases or vapors.

Dusts are airborne solids, typically ranging in size from  $0.1$  to  $25\ \mu\text{m}$ , generated by handling, crushing, grinding, impact, detonation, etc. Dusts larger than  $5\ \mu\text{m}$  settle out in relatively still air due to the force of gravity. Fumes are fine solid particles less than  $1\ \mu\text{m}$  generated by the condensation of vapors. For example, heating of lead (in smelters) vaporizes some lead material that quickly condenses to small, solid particles. Smokes are carbon or soot particles less than  $0.1\ \mu\text{m}$  resulting from incomplete combustion of carbonaceous material. Mists are fine liquid droplets generated by condensation from the gaseous to liquid state, or by the dispersion of same by splashing, foaming, or atomizing.

Gases are normally formless fluids which occupy space and which can be changed to liquid or solid by a change in pressure and temperature. Vapors are the gaseous form of substances which are normally in a liquid or solid state.

The measures for toxicity of the above substances are given in parts per million (ppm) for gases and vapors, and milligrams per cubic meter ( $\text{mg}/\text{m}^3$ ) for other airborne contaminants. The criteria for the degree of toxicity are the threshold limit values (TLVs) based on review of past research and monitory experience [early OSHA standards listed permissible exposure limit (PEL)]. TLVs are airborne concentrations of substances which are believed to represent conditions to which nearly all workers may be repeatedly exposed, eight hours a day, for lifetime employment, without any adverse effects. For acute toxins, short-term exposure levels (STELs) are indicated for a maximum of 15 minutes of exposure, not more than four times a day. Because exposures vary with time, a time-weighted average (TWA) is adopted for calculating TLVs:

$$\text{TLV(TWA)} = \sum (E_i T_i / 8) \quad (179.3)$$

where  $E_i$  is the exposure to the substance at concentration level  $i$  and  $T_i$  is the amount of time for  $E_i$  exposure in an eight-hour shift.

In many environments, there are several airborne substances present at the same time. If the effects of these substances are additive and there are no synergistic reactions, the following formula can be used for the combination of TLVs:

$$X = (C_1/T_1) + (C_2/T_2) + \cdots + (C_n/T_n) \quad (179.4)$$

where  $C_i$  is the atmospheric concentration of a substance and  $T_i$  is the TLV for that substance. If  $X < 1$ , the mixture does not exceed the total TLV; if  $X \geq 1$ , the mixture exceeds the total TLV.

## 179.5 Noise

---

Noise-induced hearing loss has been identified as one of the top ten occupational hazards by the National Institute for Occupational Safety and Health (NIOSH). In addition to hearing loss, exposure to excessive amounts of noise can increase worker stress levels, interfere with communication, disrupt concentration, reduce learning potential, adversely affect job performance, and increase accident potential [Mansdorf, 1993]. Among many types of hearing loss, sensorineural hearing loss is the most common form in occupational environments. Sensorineural hearing loss is usually caused by the loss of ability of the inner ear (cochlea nerve endings) to receive and transmit noise vibrations to the brain. In this case, the middle ear (the bone structures of malleus, incus, and stapes) and the outer ear (ear drum, ear canal, and ear lobe) may be intact.

A comprehensive and effective hearing conservation program can reduce the potential for employee hearing loss, reduce workers compensation costs due to hearing loss claims, and lessen the financial burden of noncompliance with government standards. Current OSHA standards require personal noise dosimetry measurements in areas with high noise levels. Noise dosimeters are instruments which integrate (measure and record) the sound levels over an entire work shift. Noise intensities are measured by the dBA scale, which most closely resembles human hearing sensitivity. For continuous noise levels, OSHA's permissible noise exposure is 90 dBA for an eight-hour shift. If the noise levels are variable, a time-weighted average is computed. For noise levels exceeding the limit values, an employee hearing conservation program must be administered [Mansdorf, 1993, pp. 318-320].

## 179.6 Fire Hazards

---

Fire is defined as the rapid oxidation of material during which heat and light are emitted. The National Fire Protection Association (NFPA) reported that large fire losses in the U.S. for the year 1991 exceeded \$2.6 billion. The most frequent causes of industrial fires are electrical (23%), smoking materials (18%), friction surfaces (10%), overheated materials (8%), hot surfaces (7%), and burner flames (7%). The process of combustion is best explained by the existence of four elements—fuel, oxidizer ( $O_2$ ), heat, and chain reaction. A material with a flash point below 100°F (vapor pressure  $< 40$  lb/in.<sup>2</sup>) is considered flammable, and higher than 100°F is combustible. In order to extinguish a fire, one or a combination of the following must be performed: the flammable/combustible material is consumed or removed, the oxidant is depleted or below the necessary amount for combustion, heat is removed or prevented from reaching the combustible material not allowing for fuel vaporization, or the flames are chemically inhibited or cooled to stop the oxidation reaction.

Fire extinguishers are classified according to the type of fire present. Class A involves solids which produce glowing embers or char (e.g., wood, paper). Class B involves gases and liquids which must be vaporized for combustion to occur. Class C includes Class A and B fires involving

electrical sources of ignition. Finally, Class D involves oxidized metals (e.g., magnesium, aluminum, titanium). In addition to heat, the most dangerous by-products of fires are hazardous gases and fumes, such as CO, CO<sub>2</sub>, acrolein formed by the smoldering of cellulosic materials and pyrolysis of polyethylene, phosgene (COCl<sub>2</sub>) produced from chlorinated hydrocarbons, sulfur dioxide, oxides of nitrogen (NO<sub>x</sub>) resulting from wood products, ammonia (NH<sub>3</sub>) when compounds containing nitrogen and hydrogen burn in air, and metal fumes from electronic equipment. For a complete reference to facility design requirements and exiting requirements, refer to NFPA Code 101.

## 179.7 An Engineering Approach to Hazard Control

---

As it is impossible to design an absolutely "safe" system, the following list is suggested to eliminate the critical hazards and reduce other hazards to an acceptable level (**risk control**). It is important to mention that the effectiveness of the control mechanism is diminished by using the lower items on this list.

1. Identify and eliminate the source of hazardous energy. For example, do not use high-voltage electricity. Or consider the use of noncombustible and nontoxic material in environments with fire potentials. This approach is not always practical or cost-effective.
2. Reduce the degree of hazardous energy. For example, use low-voltage solid state devices to reduce heat buildup in areas with explosion hazards. This approach is practical in some cases, yet costly in some other design applications.
3. Isolate the source of hazard. Provide barriers of distance, shields, and personal protective equipment to limit the harmful effects of the hazardous agents. To control the sequence of events in time and space, a lockout/tagout procedure is recommended.
4. Minimize failure. Include constant monitoring of critical safety parameters (e.g., gas concentrations or radiation levels). The monitoring system should detect, measure, understand and integrate the readings, and respond properly.
5. Install a warning system. Similar to consumer product warnings, all system components should be equipped with warning and proper communication systems. Operators (and the general public) should be warned of the type of hazard present and the means by which information can be obtained in case of an accident. However, too many warning signs and display indicators may confuse the operator.
6. Ensure safe procedures. A common cause of accidents is the inadequacy of procedures and the failure to follow the proper procedures.
7. Provide for backout and recovery. In case of an accident, this defensive step is taken to reduce the extent of injury and damage. This step incorporates one or more of the following actions: (a) normal sequence restoring, in which a corrective action must be taken to correct the faulty operation, (b) inactivating only malfunctioning equipment which is applied to redundant components or temporarily substituting a component, (c) stopping the entire operation to prevent further injury and damage, and (d) suppressing the hazard (e.g., spill containment of highly hazardous substances).

When hazard exposure cannot be reduced through engineering controls, an effort should be made to limit the employee's exposure through administrative controls, such as (a) rearranging work schedules and (b) transferring employees who have reached their upper exposure limits to an environment where no additional exposure will be experienced.

## 179.8 Hazard Analysis and Quantification

A number of **hazard analysis techniques** have been developed to study the hazards associated with a system. For a detailed review, see *Guidelines for Hazard Evaluation Procedures* [American Institute of Chemical Engineers, 1985]; Gressel and Gideon [1991]; Vincoli [1993]. These techniques vary in terms of their hazard evaluation approaches and the degree to which hazard exposures can be quantified. A precursor to any of these techniques is the system, which is divided into its small and manageable components, analyzed for causes and consequences of any number of potential hazards, and then synthesized to consider hazard effects on the whole system. Five hazard analysis techniques are briefly presented here.

### Preliminary Hazard Analysis

Preliminary hazard analysis (PHA) is the foundation for effective systems hazard analysis. It should begin with an initial collection of raw data dealing with the design, production, and operation of the system. The purpose of this procedure is to identify any possible hazards inherent in the system. One example is energy as the source of hazard to explore the multitude of circumstances by which an accident can occur in a system. Table 179.1 demonstrates an actual use of PHA in the design phase of metal chemical vapor deposition. The four main categories of this table are hazard, cause, main effects, and preventive control. The hazard effects and corrective/preventive measures are only tentative indicators of potential hazards and possible solutions.

**Table 179.1** A Sample for the Application of Preliminary Hazard Analysis to the Design of Metal Organic Chemical Vapor Deposition (Only Two of the Hazards Are Listed)

Hazard	Cause	Main Effects	Preventive Control <sup>a</sup>
Toxic gas release	Leak in storage cylinder	Potential for injury and fatality from large release	Develop purge system to remove gas to another tank Minimize on-site storage Provide warning system Develop procedure for tank inspection and maintenance Develop emergency response system
Explosion, fire	Overheat in reactor tube	Potential for fatalities due to toxic release and fire Potential for injuries and fatalities due to flying debris	Design control system to detect overheat and disconnect heater Provide warning system for temperature fluctuation, evacuate reaction tube, shut off input valves, activate cooling system

Adapted from Kavianian, H. R. and Wentz, C. A. 1990. *Occupational and Environmental Safety Engineering and Management*. Van Norstrand Reinhold, New York.

<sup>a</sup> This column is simplified to show the major categories of hazard control techniques.

## Failure Mode, Effects and Criticality Analysis

While PHA studies hazards in the entire system, failure mode, effects, and criticality analysis (FMECA) analyzes the components of the system and all of the possible failures which can occur. This form of analysis identifies items whose failures have a potential for hazardous consequences. In this analysis, each item's function must be determined. Once this is done, the causes and effects of the failure of the components are indicated. Then, the criticality factor of each failure is determined, and a quantified severity rating is given to the factor. Table 179.2 shows an example for FMECA. Because the frequency of each potential occurrence is also an important factor, a risk assessment matrix (depicted in Table 179.3) can be used to codify the risk assignment. A design team (including the safety engineer) can use this FMECA to redesign components or parts of the system to reduce the criticality rating to predetermined acceptable regions (preferably a hazard risk index between one and five).

**Table 179.2** A Sample for the Application of Failure Mode, Effects, and Criticality Analysis to the Metal Organic Chemical Vapor Deposition Process (Only Three System Components Are Listed)

System Component	Failure Mode	Effects	Criticality Ranking <sup>a</sup>
Reactor tube	Rupture	Release of pyrophoric gas causing fire and release of toxic gases	III
Control on reactor heater	Sensor fails; response control system fails	Reactor overheating beyond design specification	II
Refrigeration equipment	Failure to operate	Increase in vapor pressure; cylinder rupture	IV

Adapted from Kavianian, H. R. and Wentz, C. A. 1990. *Occupational and Environmental Safety Engineering and Management*. Van Norstrand Reinhold, New York.

<sup>a</sup> Criticality ranks are based on a scale from I to IV.

**Table 179.3** Hazard Risk Assessment Matrix

Frequency of Occurrence	Hazard Category			
	I Catastrophic	II Critical	III Marginal	IV Negligible
Frequent	1	3	7	13
Probable	2	5	9	16
Occasional	4	6	11	18
Remote	8	10	14	19
Improbable	12	15	17	20

Hazard Risk Index	Suggested Criteria
1-5	Unacceptable
6-9	Undesirable
10-17	Acceptable with review
18-20	Acceptable without review

## Hazard and Operability Study

Hazard and operability study (HAZOP) is one of the most tedious, yet thorough, forms of hazard analysis. It identifies potentially complex hazards in a system. HAZOP examines a combination of every part of the system and analyzes the collected data to locate potentially hazardous areas. The first step is to define the system and all specific areas from which data will be collected. This will help in deciding the HAZOP team. Next, a team of experts in these areas is assembled to analyze the collected data. The team usually consists of experts in the fields of engineering, human behavior, hygiene, organization and management, and other personnel who may have operational expertise related to the specific system being analyzed. Once this is done, an intensive information gathering process begins. All aspects of the system's operation and its human interfaces are documented. The information is then broken down into small information nodes. Each node contains information on the procedure or specific machine being used in the system. Each node is then interconnected logically with other nodes in the system. Each node is also given guide words which help identify its conditions. Table 179.4 gives an example of guide words. Each guide word is a functional representation of subsystem hazard. The team can analyze and determine the criticality or likelihood that this node could produce a hazard. At this point, the HAZOP team will need to determine what course of action to take. This procedure is one of the most comprehensive, yet time consuming, of the analysis tools. It is widely used in large and complex systems with critical safety components, such as petrochemical facilities.

**Table 179.4** HAZOP Data Table for Vacuum Air Vent Node and Reverse Flow Guide Word (Design Intention: To Vent Air into the Sterilizer following a Vacuum Stage)

Guide Word	Cause	Consequence	Recommendation
Reverse flow	Control valve leakage	Ethylene oxide leak into utility room	Air vent should not receive air from utility room, but from exhaust duct to reduce risk from reverse flow leakage of ethylene oxide

Adapted from *Hazard and Operability Study of an Ethylene Oxide Sterilizer*. 1989. National Institute for Occupational Safety and Health, NTIS Publication No. PB-90-168-980. Springfield, VA, p. 27

## Fault Tree Analysis

Fault tree analysis (FTA) uses deductive reasoning to qualitatively and quantitatively depict possible hazards which occur due to failure of the relationships between the system components (e.g., equipment, plant procedures). FTA uses a pyramid style tree analysis to start from a top undesired event (e.g., accident, injury) down to the initial causes of the hazard (e.g., a joint

separation under vibrating forces, erroneous operating procedure). There are four main types of event symbols—a fault event, basic event, undeveloped event, and normal event. A fault event is considered to be an in-between event and never the end event. A basic event is considered to be the final event. An undeveloped event is an event which requires more investigation because of its complexity or lack of analytical data. A normal event is an event which may or may not occur. Each one of these events is joined in the tree by a logic symbol. These gates explain the logic relationship between each of the events. For example, a main event is followed in the tree by two possible basic events. Either event can produce the main event. The logic gate in this case would be an *or* gate, but if both events could have contributed to the main event an *and* gate would be used. FTA's ability to combine causal events together to prevent or investigate accidents makes it one of the most powerful accident investigation and analysis tools.

## Event Tree Analysis

Event tree analysis (ETA) is similar to FTA, with the exception that ETA uses inductive reasoning to determine the undesired events which are caused by an earlier event. ETA uses the same pyramid structure as the previous analysis. However, rather than working from top to bottom, ETA works from left to right, dividing the possibility of each event into two outcomes—true (event happening), or false (event not happening). By taking an initial failure of an event, the tree designer tries to incorporate all possible desired and undesired results of the event. The advantage to this system is that it helps predict failures in a step-by-step procedure. This helps the analyst to provide a solution or a countermeasure at each analysis node under consideration. ETA's main weakness lies with its inability to incorporate multiple events at the same time.

Other techniques such as management oversight, risk tree, "what if" analysis, software hazard analysis, and sneak circuit analysis are discussed in the publications listed in the "Further Information" section.

## Defining Terms

**Compliance:** The minimum set of requirements by which an environment conforms to the local, state, and federal rules, regulations, and standards. According to the seriousness of the violation, a workplace may be cited by OSHA for imminent danger, serious violation, nonserious hazards, and de minimis violations. In addition to penalties (fines of up to \$70000 per violation), other civil and criminal charges may be brought against responsible supervisors and managers.

**Hazard:** A set of (or change in) a system's potential and inherent characteristics, conditions, or activities which can produce adverse or harmful consequences, including injury, illness, or property damage (antonym to *safety*).

**Hazard analysis techniques:** A number of analytical methods by which the nature and causes of hazards in a product or a system are identified. These methods are generally designed to evaluate the effects of hazards and offer corrective measures or countermeasures.

**Mechanical injuries:** A type of physical injury caused by excessive forces applied to human body components, such as cutting, crushing, and straining (ergonomic hazards).

**Risk control:** The process by which the probability, severity and exposure to hazards (per mission and unit of time) are considered to reduce the potential loss of lives and property.

**Toxic substances:** Those substances that may, under specific circumstances, cause injury to persons or damage to property because of reactivity, instability, spontaneous decomposition, flammability, or volatility (including those compounds that are explosive, corrosive, or have destructive effects on human body cells and tissues).

## Regulations and Standards

---

[180.1 Engineering Practices](#)

[180.2 Summary](#)

### **A. Keith Furr**

*Virginia Polytechnic Institute & State University, Retired*

Engineers and corporations have long recognized the need for the establishment of basic minimum standards for safe design and construction of structures and equipment. As a result, most major industrial groups have established associations to set guidelines for these minimum standards. However, it has been left up to the various jurisdictions to adopt any of these standards as binding. For example, fire codes are usually designed and administered locally. At least one state has virtually no fire codes that apply statewide. In other cases, the application of the codes is not universal. In the state where this author lives, only selected categories of structures are covered by the statewide code, while local building codes vary widely in their scope and interpretation depending on the local officials responsible for their administration.

After World War II, the need was recognized for "universally" applicable standards, at least in certain areas. One of the earliest of these national standards was in the field of nuclear energy, a prototype for many of the agencies which have since followed. The responsible federal agency, the Nuclear Regulatory Commission (NRC),■

The names of regulatory agencies used here are the current ones. Many of the agencies have changed names over time.

set the basic standards by which all activities involving radioactive materials created as a result of reactor-related operations were regulated. States were given the option of either allowing the federal agency to supervise the use of these materials or adopting regulations at least as stringent as the federal regulations and administer them themselves. This model has persisted in many of the other regulatory acts passed since then. In the early 1970s, the Occupational Safety and Health Act (OSHA) was passed, covering a very large number of industries. The standards in the OSHA act were, for the most part, incorporated directly from the standards and guidelines established by the industrial associations. Unfortunately, the law does not permit changes to the standards to be made easily, so that the legal standards often lag behind the industrial standards. Recently, there have been revisions to the regulatory provisions to make them more applicable to current levels of safety design.

Other major federal safety and health standards are those of the Environmental Protection Agency (EPA), the Department of Transportation, the Food and Drug Administration, the Department of Energy, the Federal Aviation Administration, and a host of other specialized

agencies. The scope of regulations is a rapidly evolving area. In recent years, federal operations have been brought under both OSHA and EPA regulations from which they were previously excluded. OSHA has taken a very active role in the operations of medical and health-related organizations with the Bloodborne Pathogens Act, and the problems of the disabled are now regulated under the Americans with Disabilities Act (ADA). A major area likely to be changed significantly in the future is noise control. Many engineers agree that the current noise safety program is too lenient. The initial threshold is likely to be changed from 90 dB to 85 dB and the doubling ratio changed from 5 dB to 3 dB. These two changes will require major engineering modifications in many cases. Another potential regulatory area that will have a significant impact on engineering design is indoor air quality, an area insufficiently researched until recently. The material in this chapter will primarily cover areas under the purview of OSHA, EPA, and the NRC.

## **180.1 Engineering Practices**

---

Incorporated in the standards for nuclear safety, and now in most other safety and health regulatory standards, was the concept of achieving compliance with safety standards wherever possible by engineering controls. For example, it should, in principle, be impossible to operate a nuclear reactor unsafely. Approaching criticality too rapidly should be impossible by having interlocks which would shut down operations automatically if this were done or if one of a number of other conditions existed, such as loss of coolant, excessively high temperatures, areas of radioactive materials, excessively high radiation levels in monitored areas, earthquakes, and loss of information in critical circuits. The control mechanisms are supposed to be designed so that redundant failures have to occur to make the operations unsafe; no single equipment failure should render operations unsafe (in the sense that an automatic or controlled shutdown should always occur should a failure occur). Of course, experience has shown that humans can bypass almost any safety feature if they try. The catwalk in the Kansas City hotel fell due to human error. The Chernobyl incident was due to a combination of a poor design, with little safety margin, and operations which were lax in maintenance, training, and function. In some cases, failure occurs due to the lack of sufficient knowledge or information. The collapse of the Tacoma Narrow Bridge in 1940, only four months after completion, is an excellent example. In any case, safety and health standards today require that, wherever feasible, safety engineering principles as identified by the regulations be the first option in complying with the standards.

Many of the earlier industrial standards, including those emphasized in the earliest versions of the OSHA standard, are intended to prevent physical injuries. Bending brakes and hydraulic presses are required to have controls making it impossible for the machines, if used properly, to injure any part of the operator's body. Grinding tools and other devices with exposed rotating components are supposed to be designed to prevent hair or clothing to be grabbed by the rotating component or for materials to be thrown by the tool and impact a person, particularly in the face and eye. The design of portable electrical tools is required to make it impossible for them to produce a shock under normal operation. Ladders, scaffolds, and guardrails are defined in great detail to prevent employees from slipping or falling. Indeed, one of the major weaknesses in the original standards was that they defined safety in such minute detail that they were seen by many

to be concerned with trivia, so that they failed in their mission to increase safety. Nevertheless, even with the original problems, most of which have now been addressed, the passing of OSHA was a major step forward in occupational safety. Not only employees benefit, but so does the general public. If a machine or structure is designed properly, it should be safe for everyone with a legitimate need and training to use the device or facility.

Other areas of the original OSHA act dealt with fire safety by adopting standards of the National Fire Prevention Association on the storage of flammable materials, limiting bulk storage, storage within facilities, and sizes of containers for appropriate classes of liquids. Similar restrictions have been established for compressed gas systems, especially gases with inherent safety problems, such as hydrogen, oxygen, and ammonia. With few changes, these regulations have remained in effect and are well understood by engineers charged with designing appropriate facilities.

Recently changes in the OSHA standard are more concerned with meeting performance specifications, allowing the engineer, owner, or user to decide how best to meet the compliance goal. Meeting safety and health regulatory standards through engineering practices is still required as the first option, with personal protective devices and procedural controls used as options when engineering controls are not practicable. A major crossroads was created a few years ago when OSHA made a distinction between industrial operations from the pilot plant scale upward and those of laboratory-scale operations. It was recognized that the designs appropriate to a large plant where a modest number of chemicals are in use, albeit on a substantial scale, are not appropriate for the laboratory environment, where literally hundreds of different chemicals are used on a rapidly changing basis. Therefore, the OSHA Laboratory Safety Act was added to the basic OSHA act, preempting the OSHA general industry standards for laboratories. Neither section of the act is more permissive than the other in terms of the intended goals, a healthy and safe environment. The two different environments do lead to substantially different engineering approaches to many problems, and engineers specializing in the two areas need to understand the differences.

One of the major issues, even in the early versions of the OSHA standards, concerns the levels of specific airborne contaminants in the workplace. For various reasons, such as toxicity, neurological risk, fetal hazards, and corrosiveness, permissible exposure levels (PELs) were set by OSHA. Theoretically, a person in good health could work an eight-hour work day without harm if the exposure levels were less than these, but could not be allowed to work if they exceeded the PELs based on an eight-hour time-weighted average. In some cases, higher short-term exposure limits (STELs) were established, and in others ceiling (C) limits were established. The initial values were essentially the threshold limit values (TLVs) recommended by the American Conference of Governmental Industrial Hygienists (ACGIH). The latter are reviewed on a yearly basis and have changed significantly. Recently OSHA attempted to change their PELs (which are legally enforceable) to be the same in most cases to the more recent values of the ACGIH (which are guidelines and are not legally enforceable). However, court actions required OSHA to rescind the changes, so the current PELs are in many cases out of date with the current available knowledge. Some states, on their own, did adopt the changed values, so now engineers must be aware of the law in their area. A conservative approach would be to design using the ACGIH guidelines since they normally provide an additional safety level. In neither case should the limits

be considered as black and white. Many factors will modify the sensitivity of a specific individual to a given contaminant; for example, a person may have reduced tolerance due to a current health condition, or natural variations in individual tolerance can occur due to heredity or sex factors. A good design practice is to maintain an action level no more than 50% of the PEL, and preferably less. Many of the newer OSHA standards now incorporate the 50% action level concept.

The importance of designing ventilation systems to remove air contaminants does not seem to be as highly appreciated by some engineers as might be expected. Routine ventilation designs for offices and homes are geared typically for temperature control. Since hot air rises, inlet and exhaust duct work and openings are typically placed in the ceiling. However most airborne contaminants are heavier than air, so general room exhausts for these contaminants should be located close to the floor, or no lower than waist high. The air flow should not be such as to draw or discharge contaminated air indoors through an individual's breathing zone. Various recommendations exist for the amount of fresh air needed depending on the type of occupancy. Typically, in an office environment a value of 20 cubic feet per minute (cfm) of fresh air is recommended. Relatively few older structures meet this requirement. In chemically contaminated areas, such as laboratories, the number of air changes per hour is often used as a criterion, with current levels being 10 to 12 per hour. This has serious implications for laboratories since the normal requirement is for this to be 100% fresh air. In office structures the air is normally partially recycled so that only 15% to 30% may be fresh.

The recycling of air in newer energy-efficient buildings appears to be at least partly responsible for the increasing evidence of health problems in these tight buildings. Recycling air can cause a problem which exists in one part of a building to eventually spread throughout the building. This is especially true when the system is itself the cause of the problem. Most duct systems are not designed for ease of cleaning, and over time become dirty. The dirt and grease which builds up in these systems is an ideal breeding ground for molds and bacteria, to which many individuals are allergic. Not only should high-efficiency filters be used and replaced frequently, but the duct work interior needs to be cleaned periodically. If air quality is brought under regulations, there will be significant engineering requirements on the design of the systems to facilitate cleaning, on filter designs, and on the selection of materials for construction to limit the emission of volatile organic compounds. There is increasing evidence that long-term exposure to some organics, such as formaldehyde, may cause problems to hypersensitive individuals at levels very much below the permissible PELs or TLVs. The National Institutes of Occupational Safety and Health (NIOSH) already are recommending levels substantially below those of both OSHA and the ACGIH for a number of materials due to these low, continuous exposures. Unfortunately, our knowledge of health effects in general and especially those related to long-term exposures at low levels leaves a great deal to be desired, although it is improving. Statistically, the problem with low levels of airborne contaminants is very much like the situation with low levels of radioactivity. The problems may exist, but the experimental evidence is virtually impossible to obtain because of the extremely large number of subjects required for direct measurement.

The most effective and energy-conserving means of controlling contaminants is to capture them at the source. In a factory large-scale scavenging systems may be appropriate, while in laboratories it would be appropriate to require that all work with the potential to release hazardous vapors,

fumes, or gases be done in fume hoods with at least 100 feet per minute (fpm) face velocity.

Once contaminated air has left a facility, it is hoped that it will be diluted to a level that is safe. Air pollution standards have been established which may or may not be sufficient. Problems such as acid rain and ozone depletion are well documented in the literature and have been extensively publicized in the media. In laboratory buildings, for example, engineers until quite recently typically placed rain caps over fume hood exhausts so that the contaminated air was forced back onto the roof of a building and in many cases was recaptured by the building air system. Often, once a laboratory building was completed, subsequent modifications added fume hoods to a duct system which did not have the capacity to handle them. Fire codes typically require laboratories to be at negative pressure with respect to the corridors so that fire within a laboratory cannot spread via the corridors. However, the negative pressure also prevents contaminated air from spreading via the corridors as well. Exhaust ducts for the newer hoods were often allowed to penetrate floors intended to be fire separations. All of these practices violated standards recommended by either the ACGIH, NFPA, or American Society of Heating, Refrigerating and Air Conditioning Engineers (ASHRAE). Since many of the standards have now been adopted by OSHA, a strong national regulatory agency is charged with enforcing the basic standards.

The Environmental Protection Agency has been a major factor in changing engineering practices. One of the most significant standards recently enacted dealt with underground petroleum storage tanks. A large percentage of organizations with a substantial number of employees, including industries, transportation departments, hospitals, and universities, have either heating oil tanks or gasoline tanks which are buried. Tanks which have been buried for 20 years or more have an increasing probability of leaking as they age. The EPA regulation requires all of these tanks above a certain capacity to be protected from leaking into the environment by 1998. Typically, this will involve replacing a tank with a double-shelled unit equipped with appropriate sensors to ensure that leaking does not occur. If environmental contamination has already occurred, the owner is required to clean up the contaminated site. This law alone has generated immense growth in engineering firms specializing in testing, abating, and replacing these sites.

Although addressed in **Chapter 89**, the related issue of prevention of ground contamination from landfills will be briefly mentioned here. In the last five years, a very large number of landfills have been closed due to the enactment of strict standards on landfills. Although no responsible person would deliberately dispose of any kind of hazardous waste routinely at a municipal landfill, it is estimated that 3 to 5% of all municipal solid waste could be characterized as hazardous waste, primarily from households and small business establishments. To lengthen the life of existing landfills, and to reduce the cost of new ones, recycling programs have been growing dramatically and have given rise to their own engineering disciplines. Alternative means of hazardous and solid waste disposal have been developed to reduce or eliminate the burial of wastes which could remain hazardous for thousands of years. Various incineration methods have been developed, which must comply with EPA's clean air standards as well as being subject to the "not-in-my-back-yard" (NIMBY) syndrome. Dozens of techniques have been developed specifically for disposal of medical wastes, which are regulated by state programs of varying stringency. No matter what engineering approach is involved in any of these environmental issues (and others not mentioned),

the net result must be to reduce the level of contaminants in the soil or air below a regulatory defined level either by destruction or by modification. Underground burial has been deemed unacceptable for most hazardous materials, with the notable exception of radioactive isotopes, for whose destruction no practical means exist. The major regulatory act which sets standards for the disposition of materials with hazardous properties is the Resource Conservation and Recovery Act (RCRA). Since most facilities do not process their hazardous waste locally, packaging and transportation of these materials must also meet the requirements of the Department of Transportation. These standards have changed significantly within the past five years and now are generally consistent with comparable international requirements.

Another major EPA standard is the community-right-to-know standard. Under this act, communities must be made aware of potential industrial chemical hazards in their areas.

The original standards for making buildings accessible to the handicapped were less successful than desired, so the Americans With Disabilities Act was passed in the early 1990s. This standard is much more stringent and carries the potential for much more severe penalties. Not only are the familiar wheelchair ramps and modified bathroom facilities required, but a number of other engineering changes are specified as well. Safety equipment, such as safety showers and eyewash fountains, must now meet specifications to ensure that a disabled person can use them. Fire alarms must provide a high-intensity visual alarm as well as an audible alarm. Doors must provide means to prevent a disabled person from being trapped or injured by the opening and closing mechanism. Instructions on public signs, including safety signs, must be provided in braille where appropriate. Meetings which could be attended by the disabled must ensure that the information can be received by a disabled person. This could include audio and or visual equipment for the hearing or visually impaired, or possibly a sign-language interpreter. The availability of these resources must be made known at the time the meeting is announced. Places of refuge must be identified to which disabled persons could retreat while awaiting rescue in the event of a fire or other incident. All new facilities must be designed to comply with the standard, and older ones will have to be brought toward full compliance.

The Food and Drug Administration not only establishes standards for nutritional information and for such things as drugs, pesticides, and residues of these materials on foods, but also regulates or provides guidelines for the design of x-ray machines, lasers, microwave units, and other generators of electromagnetic emissions. Most of their safety standards are intended as requirements for the manufacturer and effectively require engineering safeguards to be incorporated in these devices which a user cannot easily bypass. For example, industrial x-ray cameras are required to be interlocked so that the intense radiation areas within the target area cannot be accessed while the beam is on. The radiation levels within this area are such that a serious radiation burn to the hands can occur within 30 seconds. Requirements for the design of x-ray units for diagnostic tests now mandate that the unit define the exposed target area by light so that areas other than the one of interest are not exposed. Similar restrictions are imposed on lasers which have sufficient power to cause blindness if a beam were to reach the eye directly or by non-diffuse reflection. The standards also include guidelines for the safe use of the equipment by the operators, although these are recommendations only and are not legally binding. The ACGIH has established TLVs for laser exposures as well as for chemical exposures.

The NRC does not regulate radiation exposures due to x-rays or the use of radioactive materials not related to by-product materials (materials made radioactive by reactor operations). However, dose rates for x-rays are generally equivalent to those for radiation from radioactive materials. Also, states typically regulate the radioactive materials not covered by the NRC in a comparable fashion. In January 1994 the NRC regulations were changed in several significant ways. For example, exposure limits, which had been primarily concerned with external exposures, now must incorporate exposures due to ingestion, inhalation, and possible percutaneous absorption; certain external limits were changed, including those related to the extremities, which now include the area below the knee as well as the areas beyond the elbows, since there are no critical organs within those bodily components; and women who may be pregnant (and so declare) must be limited to 10% of the whole body exposure permissible for other monitored employees, in order to limit the exposure to the fetus. The NRC has also stepped up the stringency with which it monitors compliance, and in recent years it has become commonplace for the NRC to impose substantial fines on industrial users, hospitals, and universities.

Also in 1994 the EPA activated a law which had been on the books since 1989 but had not been enforced. This standard limits the dispersion of radioactive materials into the atmosphere if it is possible that they may be taken into the body directly or through the food chain. This standard has a potential impact on the research use of radioactive materials since much of the common applications of radioactive materials are in research institutions, where radioactive materials are emitted in fume hood exhausts. A radioisotope in very common use is  $^{125}\text{I}$ . This isotope is readily taken up by the body and is concentrated in the thyroid. For operations that are limited due to this regulation, it is apt to be due to this isotope.

There are other standards and guidelines which have a significant impact on safety and health. Among these are the OSHA Hazard Communication Act (29 CFR 1910.1200) for industrial users of hazardous materials, and its companion for laboratory employees (OSHA 29 CFR 1450). Both require extensive training of employees and provision for responses to emergencies. The previously mentioned Bloodborne Pathogens Act (OSHA 29 CFR 1919.1030) is a very strong standard. All of these incorporate significant engineering requirements to protect employees through either provision of emergency measures or uses of protective equipment.

The National Institutes of Health (NIH) Guidelines for Research Involving Recombinant DNA Molecules represent a significant standard which is, in effect, a regulation although it is labeled a guideline. Research programs which do not comply with these guidelines will not receive funding from NIH. Characteristics of the facility in which the research is done, the procedures which are followed, and the experimental subjects are all carefully defined by the standard. Further, any genetically engineered products of these researches must receive explicit approval prior to being placed on the market. In a similar vein, the Centers for Disease Control has published standards governing microbiological research practices based on concerns that not only research workers might contract a contagious disease. This care is not due to a high probability that contagion may spread beyond the facility, as in fact this has not been known to occur in this country, but is designed to ensure that it does not. A disturbing trend is that our disease-fighting capabilities are rapidly decreasing in efficacy as infectious organisms become immune to previously effective treatments.

## 180.2 Summary

---

The preceding material represents a very brief overview of the regulatory environment. Any one of the topics mentioned would justify a fully detailed exposition in a book, if not an entire book, to be covered adequately. There are topics which were not mentioned at all that are of comparable importance to those covered. Safety and health programs, once developed only voluntarily by enlightened organizations, due to their recognition that it was cost-effective, are now virtually completely defined by regulations and standards applicable to the substantial majority of employees. Engineering subdisciplines have developed to provide the supportive infrastructure for the regulations. This is a rapidly developing field. Many of the regulations cited did not exist five years ago, and every one of them has undergone significant changes in that time.

There is a tendency to believe that regulations stifle productivity. This may be so if the regulations are applied inflexibly, without common sense. A sensible safety program will without doubt improve productivity. One of the country's most profitable companies is E. I duPont, which pioneered many of the safety programs later incorporated into standards. They are generally regarded as having one of the very best safety and health programs in industry. They are not doing it for their health or to be nice. They know their program is cost-effective.

## References

No date is given for the citations of regulatory standards. These undergo continual revision. The most current version should always be used.

## Further Information

For information on the topic of regulations in safety, there is, of course, no complete substitute for the regulations themselves. They are being changed on almost a daily basis. In addition, the regulations themselves are being interpreted by the administering agencies. Each agency publishes an annual update, and the *Federal Register* is available as printed text and is now available on CD-ROM and as an on-line electronic service. The following two references provide a useful means of keeping track of the changes and their interpretations. The second one lists equipment which is available to comply with the standards, and sources for the equipment.

Bureau of National Affairs, Rockville, MD: Publications covering occupational safety, environmental safety and health, chemical safety, and hazardous waste management, providing frequent regular updates.

"An Act to Promote the Progress of Useful Arts," was the first patent statute in the United States. It was signed by George Washington on April 10, 1790 and became law. The intention of the Patent Act was to protect inventor's rights to their inventions. Initially, each inventor was required to submit a drawing, description, and a miniature working model built to scale. Three cabinet heads examined each application and granted patents "for any such useful art, manufacture, engine, machine, or device as deemed sufficiently useful and important." The system quickly became so cumbersome that it was dissolved three years later.

A second Patent Act was passed in 1793 which eliminated the examination procedure and established a simple registration system and a flat \$30 fee. This system automatically granted patents; however, the merit of the invention was deferred. Eli Whitney's 1794 patent for the cotton gin made him famous, but he

realized few financial rewards because the new patent system failed to protect the right of the inventor. This system remained in place for 43 years.

The Patent Act of July 4, 1836 reinstated the American patent system and provided protection for investors and their inventions. In a speech given in 1859, Abraham Lincoln said the U.S. patent system "added the fuel of interest to the fire of genius." Today, the Patent and Trademark Office operates under the same examination system.

The photograph is of the old Patent Office Building around 1917. The Patent Office remained in this building until 1932. Today, the U.S. Patent and Trademark Office is located at the Crystal Plaza in Arlington, Virginia. (Photo courtesy of the U.S. Patent and Trademark Office.)

THE SUCCESS OF ANY ENGINEERING PROJECT for production or service is inextricably linked to economics and management issues related to that project. Engineers who act as project managers are often called upon to make informed economic and managerial decisions. This section intends to help readers to understand the basic concepts and analytical tools of engineering economics and management.

Investment in a capital project involves the commitment of resources of an organization in anticipation of greater returns in the future. Based on the generally accepted objective of maximizing the return, a merit measure is identified and a decision criterion is established for evaluation of the merit of a project. The two most common merit measures are present worth (also called net present value) and internal rate of return. The present worth analysis is based on the net value of a project calculated by discounting all cash flows over time to the present according to a predetermined discount rate. The internal rate of return is based on the average annual percentage return over the life of an investment. For either merit measure, a corresponding decision criterion must be used for project selection. More generally, decision rules are introduced for three classes of project selection problems: to accept or reject a proposed project, to select the best among a group of mutually exclusive alternatives, and to select a group of noncompeting projects under budget constraint.

The basic concepts have been extended to cover real issues in the business world. One aspect is depreciation and corporate taxes imposed by tax laws and regulations. Another is the financing decision to obtain funds for a project either through issuing debt and equity securities (bonds and stocks) in the capital market or through leasing to avoid a large capital outlay. The decision maker must also consider the uncertainty of various factors in economic analysis. Risk assessment provides information about the risk exposure inherent in a given decision and takes into consideration the risk attitude of the decision maker. Sensitivity analysis allows the decision maker to measure the impact resulting from changing values of uncertain variables on the investment returns.

Application of principles of economic analysis to engineering production and service requires the consideration of operational requirements, performance and maintenance effectiveness, production quantity, utilization factors, logistic support, and disposal. Life-cycle costing involves such decisions to minimize the discounted cost from the life cycle of a project. Evaluation of complex projects from product development to organizational improvement requires the integration of both analytical and judgmental techniques in order to select and fund the best project. Another analytical tool for planning, scheduling, and controlling time and cost of a project is the critical path method, which utilizes a network-based model to represent the interrelationships of project activities.

The profit of an organization may also be enhanced by royalties derived from intellectual properties such as patents, copyrights, trademarks, and licenses, which are protected by intellectual

property laws. The owner of a copyrighted product can enter into a license agreement in which the licensee can distribute and reproduce the product in return for royalties payable to the licensor-owner.

## Present Worth Analysis

---

### 181.1 Calculation

Analysis Period • Cash Flows • Discount Rate

### 181.2 Application

### 181.3 Other Considerations

Savings Versus Income/Returns • Uncertainty • Externalities

### Walter D. Short

*National Renewable Energy Laboratory*

Evaluation of any project or investment is complicated by the fact that there are usually costs and benefits (i.e., cash flows) associated with an investment that occur at different points in time. The typical sequence consists of an initial investment followed by operations and maintenance costs and returns in later years. Present worth analysis is one commonly used method that reduces all cash flows to a single equivalent cash flow or dollar value (Palm and Qayum, 1985). If the investor did not care when the costs and returns occurred, **present worth** (also known as *net present value*) could be easily calculated by simply subtracting all costs from all income or returns. However, to most investors the timing of the **cash flows** is critical due to the time value of money; that is, cash flows in the future are not as valuable as the same cash flow today. Present worth analysis accounts for this difference in values over time by discounting future cash flows to the value in a base year, which is normally the present (hence the term "present" worth). If the single value that results is positive, the investment is worthwhile from an economic standpoint. If the present worth is negative, the investment will not yield the desired return as represented by the discount rate employed in the present worth calculation.

### 181.1 Calculation

---

The present worth (PW), or net present value, of an investment is

$$PW = \sum_{t=0}^N \frac{C_t}{(1+d)^t} \quad (181.1)$$

where  $N$  is the length of the analysis period,  $C_t$  is the net cash flow in year  $t$ , and  $d$  is the **discount rate**.

## Analysis Period

The analysis period must be defined in terms of its first year and its length, as well as the length of each time increment. The standard approach, as represented in Eq. (181.1), is to assume that the present is the beginning of the first year of the analysis period [ $t = 0$  in Eq. (181.1)], that cash flows will be considered on an annual basis, and that the analysis period will end when there are no more cash flows that result from the investment (e.g., when the project is completed or the investment is retired) [Ruegg and Petersen, 1987]. For example, the present worth for a refinery that will require 6 years to construct and then last for 30 years (to 2031) can be represented as

$$PW(1995) = \sum_{t=0}^{36} \frac{C_t}{(1+d)^t} \quad (181.2)$$

In this case the analysis period covers both the construction period and the full operation period, as shown in Fig. 181.1. In Eq. (181.2) the parenthetical (1995) explicitly presents the base year for which the present worth is calculated. This designation is generally omitted when the base year is the present.

**Figure 181.1** Analysis period for a refinery.

However, any of these assumptions can be varied. For example, the present can be assumed to be the first year of operation of the investment. In the refinery example the present worth can be calculated as if the present were 6 years from now (2001)—that is, the future worth in the year 2001—with all investment costs between now and then accounted for in a single turnkey investment cost ( $C_0$ ) at that time ( $t = 0$ ). In this case the base year is 2001.

$$PW(2001) = \sum_{t=0}^{30} \frac{C_t}{(1+d)^t} \quad (181.3)$$

The length of the analysis period is generally established by the point in time at which no further costs or returns can be expected to result from the investment. This is typically the point at which the useful life of the investment has expired. However, a shorter lifetime can be assumed with the cash flow in the last year accounting for all subsequent cash flows. For the refinery example the analysis period could be shortened from the 36-year period to a 26-year period, with the last year

capturing the salvage value of the plant after 20 years of operation.

$$PW = \sum_{t=0}^{26} \frac{C_t}{(1+d)^t} \quad (181.4)$$

where  $C_{26}$  is now the sum of the actual cash flows in  $C_{26}$  and the salvage value of the refinery after 20 years of operation. One common reason for using a shorter analysis period is to assess the present worth, assuming sale of the investment. In this case the salvage value would represent the price from the sale minus any taxes paid as a result of the sale.

Finally, the present worth is typically expressed in the dollars of the base year. However, it can be expressed in any year's dollars by adjusting for inflation. For example, in the refinery case, in which the base year is 2001 [Eq. (181.3)], the present worth value expressed in the dollars of the year 2001 can be converted to a value expressed in today's (1995) dollars, as follows:

$$PW_{1995\$}(2001) = \frac{1}{(1+i)^{2001-1995}} PW_{2001\$}(2001) \quad (181.5)$$

where  $i$  is the annual **inflation rate** between 1995 and 2001 and the subscripts indicate the year of the dollars in which the present worth is presented.

## Cash Flows

Cash flows include all costs and returns where costs are negative and returns or income are positive (see [Fig. 181.2](#)). The cash flow for each year of the analysis period must include all actual costs and income associated with the investment during that year. Thus, cash flows must include all initial capital costs, all taxes, debt payments, insurance, operations, maintenance, income, and so forth.

**Figure 181.2** Cash flows.

Cash flows are typically expressed in terms of the actual dollar bills paid or received (**nominal** or current **dollars**). Alternatively, cash flows can be expressed in terms of the dollars of a base year (**real** or constant **dollars**). Nominal dollar cash flows,  $C^n$ , can be converted to real dollar cash flows,  $C^r$ , (and vice versa) by accounting for the effects of inflation

$$C_0^r = \frac{C_t^n}{(1+i)^t} \quad (181.6)$$

where  $i$  is the annual inflation rate and  $t$  is the difference in time between the base year ( $t = 0$ ) and the year of the nominal dollar cash flow.

A discounted cash flow is the present worth of the individual cash flow. Discounted cash flow in period  $s$  equals

$$\frac{C_s}{(1+d)^s} \quad (181.7)$$

As shown in [Fig. 181.2](#) (which used a nominal discount rate of 0.2 or 20%), discounting can significantly reduce the value of cash flows in later years.

## Discount Rate

The discount rate is intended to capture the time value of money to the investor. The value used varies with the type of investor, the type of investment, and the opportunity cost of capital (i.e., the

returns that might be expected on other investments by the same investor). In some cases, such as a regulated electric utility investment, the discount rate may reflect the weighted average cost of capital (i.e., the after-tax average of the interest rate on debt and the return on common and preferred stock). Occasionally, the discount rate is adjusted to capture risk and uncertainty associated with the investment. However, this is not recommended; a direct treatment of uncertainty and risk is preferred (discussed later).

As with cash flows, the discount rate can be expressed in either nominal or real dollar terms. A nominal dollar discount rate must be used in discounting all nominal dollar cash flows, whereas a real discount rate must be used in discounting all real dollar cash flows. As with cash flows, a nominal dollar discount rate,  $d_n$ , can be converted to a real dollar discount rate,  $d_r$ , by accounting for inflation with either of the following:

$$1 + d_n = (1 + d_r)(1 + i)$$

$$d_r = \frac{1 + d_n}{1 + i} - 1 \quad (181.8)$$

Since cash flow should include the payment of taxes as a cost, the discount rate used in the present worth calculation should be an after-tax discount rate (e.g., the after-tax opportunity cost of capital).

## 181.2 Application

---

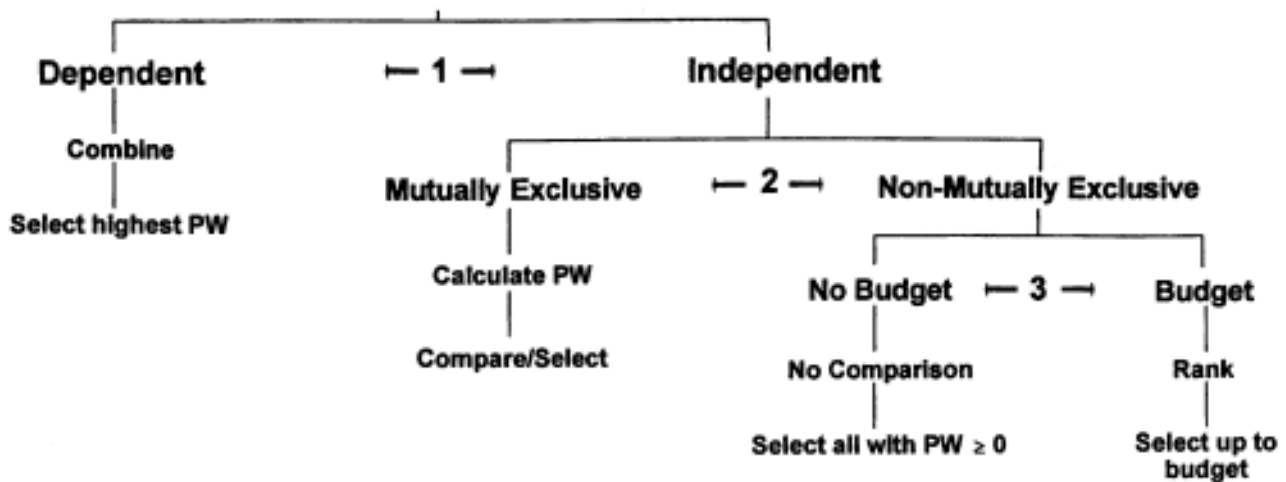

Present worth analysis can be used to evaluate a single investment or to compare investments. As stated earlier, a single investment is economic if its present worth is equal to or greater than zero but is not economic if the present worth is less than zero.

PW > 0. The investment is economic.

PW < 0. The investment is not economic.

The use of present worth to compare multiple investments is more complex. There are several possible situations, as shown in Fig. 181.3, including investments that impact one another (dependence, point 1 on Fig. 181.3), investments that are mutually exclusive (only one investment is possible from a set of investments, point 2 on Fig. 181.3), and/or investments for which there is a budget limitation (point 3 on Fig. 181.3).

**Figure 181.3** Comparison of investments.

If the investments do have an impact on one another (i.e., they are dependent), then they should be considered both together and individually. Investments that impact one another are reevaluated as a package, with new cash flows representing the costs and returns of the combination of investments. The present worth of all individual investments and all combinations of dependent investments should then be compared. This comparison will, by definition, include some mutually exclusive investments (i.e., they cannot all be undertaken because some are subsumed in others). Each set of these mutually exclusive alternatives can be resolved to a single alternative by selecting the combination or individual investment with the highest present worth from each set. For example, if a refinery and a pipeline are being considered as possible investments and the pipeline would serve the refinery as well as other refineries, then the presence of the pipeline might change the value of the refinery products (i.e., the two investments are not independent). In this case the present worth of the refinery alone, the present worth of the pipeline alone, and the present worth of the combined pipeline and refinery should be calculated and the one with the highest present worth selected.

Once each set of dependent investments has been resolved to a single independent investment, then the comparison can proceed. If only one investment can be made (i.e., they are mutually exclusive), then the comparison is straightforward; the present worth of each investment is calculated and the investment with the highest present worth is the most economic. This is true even if the investments require significantly different initial investments, have significantly different times at which the returns occur, or have different useful lifetimes. Examples of mutually exclusive investments include different system sizes (e.g., three different refinery sizes are being considered for a single location), different system configurations (e.g., different refinery configurations are being considered for the same site), and so forth.

If the investments are not mutually exclusive, then one must consider whether there is an overall budget limitation that would restrict the number of economic investments that might be undertaken. If there is no budget (i.e., no limitation on the investment funds available) and the investments have no impact on one another, then there is really no comparison to be performed and the investor simply undertakes those investments that have positive present worth and discards those that do not.

If the investments are independent but funds are not available to undertake all of them (i.e., there is a budget), then there are two approaches. The easiest approach is to rank the alternatives, with the best having the highest benefit-to-cost ratio or savings-to-investment ratio. (The investment

with the highest present worth will not necessarily be the one with the highest rank, since present worth does not show return per unit investment.) Once ranked, those investments at the top of the priority list are selected until the budget is exhausted. Present worth can be used in the second, less desirable approach by considering the total present worth of each combination of investments whose total initial investment cost is less than the budget. The total present worth of the investment package is simply the sum of the present worth values of all the independent investments in the package. That combination with the greatest present worth is then selected.

## 181.3 Other Considerations

---

Three commonly encountered complications to the calculation of present worth are savings versus returns, uncertainty, and externalities.

### Savings Versus Income/Returns

In many, if not most, investments, the positive cash flows or benefits are actual cash inflows that result from sales of products produced by the investment. However, there are also a large number of investments in which the positive cash flows or benefits are represented by savings. For example, the benefit of investing in additional insulation for steam pipes within a refinery is savings in fuel costs (less fuel will be required to produce steam). These savings can be represented in a present worth evaluation of the insulation as positive cash flows (i.e., as income or returns).

### Uncertainty

In the present worth discussion up to this point, it has been assumed that all the input values to the present worth calculation are known with precision. In fact, for most investments there is considerable uncertainty in these values—especially the future cash flows. The preferred method for including such uncertainties in the calculation of present worth is to estimate the probability associated with each possible cash flow stream, calculate the present worth associated with that cash flow stream, and assign the probability of the cash flow to the present worth value. This will produce one present worth value and one probability for each possible cash flow stream (i.e., a probability distribution on the present worth of the investment). This distribution can then be used to find statistics such as the expected present worth value, the standard deviation of the present worth value, confidence intervals, and so forth. These statistics, especially the expected present worth value and confidence intervals, can then be used in the decision process.

### Externalities

In many cases not all costs and benefits are included in the cash flows because they are not easily quantified in terms of dollars or because they do not benefit or cost the investor directly. Such costs and benefits are referred to as *externalities* because they are generally considered external to the

direct economic evaluation (i.e., they are not included in the present worth calculation). For example, the cost of air emissions from a refinery are often not considered in a present worth calculation, even though they impact the local community as well as the employees of the refinery. Such emissions may result in lost work days and more sick pay, as well as the loss of the local community's goodwill to the refinery, making future refinery expansion more difficult. Likewise, emissions may affect the health and quality of life of local residents.

Externalities can be considered qualitatively, along with measures such as the present worth, when evaluating an investment. Or externalities can be explicitly considered within a present worth calculation by estimating their costs and benefits in terms of dollars and including these dollars in the present worth cash flows. In this case these costs and benefits are said to have been *internalized* and are no longer externalities.

## Defining Terms

**Analysis period:** The period during which the investor will consider the costs and benefits associated with an investment. This period is usually determined by the period during which the investor will develop, operate, and own the investment.

**Cash flow:** The dollar value of all costs and benefits in a given period. Cash flows are normally expressed in nominal dollars, but can be expressed in real dollars.

**Discount rate:** The interest rate that represents the time value of money to the investor. For most investors this is the opportunity cost of capital (i.e., the rate of return that might be expected from other opportunities to which the same capital could be applied). Discount rates can include inflation (nominal discount rate) or exclude inflation (real discount rate).

**Inflation rate:** The annual rate of increase in a general price level, frequently estimated as the gross domestic product deflator or the gross national product deflator. Estimates of future value are generally provided by macroeconomic forecasting services.

**Nominal dollars:** Current dollars; dollars in the year the cost or benefit is incurred (i.e., number of dollar bills).

**Present worth:** Net present value. The sum of all cash flows during the analysis period discounted to the present.

**Real dollars:** Constant dollars; value expressed in the dollars of the base year. Real dollars are the value excluding inflation after the base year.

# Project Analysis Using Rate-of-Return Criteria

---

- 182.1 Net Present Value
- 182.2 Internal Rate of Return
- 182.3 Overall Rate of Return
- 182.4 Project Investment Base
- 182.5 Scale-Adjusted ORR
- 182.6 Project Life Differences
- 182.7 Conclusion

**Robert G. Beaves**

*Robert Morris College*

Many decision makers find rate-of-return investment criteria to be more intuitive and therefore easier to understand than net present value (NPV). As a result the internal rate of return (IRR) continues to be widely used despite its legendary quirks and the well-established superiority of NPV. A second rate-of-return criterion, the overall rate of return (ORR), provides more NPV consistency than does the IRR but is not widely known or used. This chapter compares NPV, IRR, and ORR and demonstrates some shortcomings of rate criteria.

## 182.1 Net Present Value

---

A project's **net present value** (NPV) represents *the change in the value of the firm* that occurs if and when the firm implements that project. The NPV of a project is calculated by summing the present values of all cash flows associated with it while preserving negative signs of flows to the project and positive signs of flows from the project. NPV can be defined as follows:

$$\text{NPV} = \sum_{t=0}^n a_t(1+k)^{-t} \quad (182.1)$$

where

- $a_t$  = the cash flow at the time  $t$  (end of period  $t$ )
- $k$  = the firm's opportunity cost; the discount or "hurdle" rate
- $n$  = the number of periods in the project's life.

Implementation of projects with positive NPVs increases firm value, whereas implementation of projects with negative NPVs reduces it. Because management's goal is to maximize firm value, a project should be rejected if its NPV is negative and accepted otherwise. When forced to choose among competing positive-NPV projects, the project that offers the highest NPV should be preferred. It is well established that the NPV criterion provides theoretically correct accept/reject and project-ranking decisions.

## 182.2 Internal Rate of Return

A project's **internal rate of return** (IRR) is that discount rate  $k^*$  for which that project's NPV would be zero. Note that a project's IRR is independent of the firm's actual hurdle rate  $k$ . A project's IRR represents *the average periodic rate of return earned on funds while they are invested in that project*. Because IRR is an average rather than a constant rate, the rate or return generated by a project in any one period need not equal its IRR.

Consider project A in [Table 182.1](#), which has an IRR of 12.48%. Project A's rate of return during the first period (time 0 to time 1) is unknown. The "balance" in project A at time 1 need not be \$1125 (\$700 released to the firm and \$525 remaining in the project) as would be the case if its 12.48% IRR was a constant rate. Although a project's IRR represents the average rate of return earned on funds invested in that project, the amount of funds so invested varies from period to period and is often unknown.

**Table 182.1** Projects A, B, and C\*

	Project A	Project B	Project B–A	Project C
Time				
0	–1000	–1000	0	–2000
1	700	0	–700	1400
2	300	0	–300	600
3	200	1423	1223	400
Method				
IRR	12.48%	12.48%	12.48%	12.48%
NPV	\$34.56	\$69.12		\$69.12
IB	\$1000.00	\$1000.00		\$2000.00
ORR	11.25%	12.48%		11.25%
ORR <sub>2000</sub>	10.63%	11.25%		11.25%

\* $k = 10\%$

A project should be rejected if its IRR is less than the firm's **opportunity cost**  $k$  and accepted otherwise. NPV and IRR provide the same accept/reject decisions for projects that have unique IRRs. The use of IRR for accept/reject decisions is complicated, however, by the fact that some projects have multiple IRRs whereas others have none.

It is well established that ranking competing projects on the basis of their IRRs can provide an incorrect choice from among those projects. Consider projects A and B in [Table 182.1](#). Both projects require initial investments of \$1000 and both have the same IRR, 12.48%. No clear

preference exists between projects A and B if ranked on the basis of their IRRs. Nonetheless, project A's NPV is only \$34.56, whereas project B's is \$62.12. Project B has a high NPV because its entire initial investment and all accumulated returns on that investment remain in the project, earning an average 12.48% rate for three periods. On the other hand, much of project A's initial investment and accumulated returns are released before the end of its 3-period life.

Any two projects can be correctly ranked by examining the IRR of an incremental or "difference" project. Project B–A in [Table 182.1](#) is an incremental project for projects A and B created by subtracting each cash flow of A from the respective cash flow of B. Because the IRR of incremental project B–A exceeds the firm's 10% opportunity cost, project B (the project from which a second project was subtracted) should be preferred over A. If the IRR of the incremental project was less than  $k$ , project A would have been preferred. Because incremental IRR analysis can only provide pair-wise rankings, its use becomes tedious where more than two projects are being ranked. Further, an incremental project may have multiple IRRs or no IRR at all.

## 182.3 Overall Rate of Return

---

A project's **overall rate of return** (ORR) represents the *average periodic rate earned on a fixed investment amount* over the expected life of the project. That fixed investment amount is known as the project's **investment base**. A project's ORR can be defined as:

$$\text{ORR} = \left[ \frac{(\text{IB} + \text{NPV}) \times (1 + k)^n}{\text{IB}} \right]^{1/n} - 1.0 \quad (182.2)$$

where

NPV = the project's NPV, with  $k$  as discount rate

IB = the project's investment base; to be defined in greater detail later.

In calculating a project's ORR, that project's investment base plus any accumulated returns are assumed to earn the project's IRR while invested in it and to earn the firm's opportunity cost when not needed by the project. Thus project B in [Table 182.1](#) has an ORR of 12.48% because, for its entire 3-period life, its \$1000 investment base and all accumulated returns remain invested in the project earning its 12.48% IRR. Project A's ORR is less because significant amounts of its investment base and accumulated returns are released at times 1 and 2 and earn the firm's 10% opportunity cost for the balance of that project's life.

Projects with ORRs greater than or equal to the firm's opportunity cost  $k$  should be accepted, whereas those with lower ORRs should be rejected. As Eq. (182.2) suggests, the ORR always provides accept/reject decisions that are consistent with those provided by NPV. In contrast to the IRR, the ORR is uniquely defined for all projects and is generally a function of the firm's opportunity cost  $k$ . Further, the ORR provides an NPV-consistent ranking of competing projects that have the same scale or investment base IB.

When comparing projects having different investment bases, ORRs adjusted to some common

scale will provide an NPV-consistent ranking. Scale adjustments are required because the ORR, like all rate criteria, does not preserve scale. Consider project C (Table 182.1), which was created by doubling project A's cash flows. Although a project's NPV doubles when its size is doubled, its IRR and ORR are unchanged. Scale is lost in the calculation of any rate of return, an important shortcoming in ranking competing projects.

## 182.4 Project Investment Base

A project's investment base represents the time 0 value of all external funds (i.e., funds not provided by the project itself) needed to finance the project. All projects considered thus far required a single cash inflow (i.e., negative flow), which occurred at time 0. The investment base of such projects is simply the amount of that initial inflow,  $-a_0$ . Because some projects have more complex cash flow patterns, it is necessary to establish the following general rule for determining a project's investment base:

A project's investment base is determined by multiplying the minimum cumulative present value associated with its cash flows times  $-1.0$ .

Consider project D in Table 182.2, for which the firm's opportunity cost is assumed to be 10%. Using 10% as the discount rate, present values and cumulative present values are calculated for each of project D's cash flows. The minimum cumulative present value associated with project D's cash flows is  $-\$1057.85$ . Thus project D's investment base is  $\$1057.85$ . Assuming a 10% opportunity cost for all funds not currently needed by project D,  $\$1057.85$  is the minimum time 0 amount that will fund project D to its termination at time 5.

**Table 182.2** Project D\*

	Cash Flow ( $a_t$ )	Present Value	Cumulative PV
Time			
0	-1000	-1000.00	-1000.00
1	300	272.73	-727.27
2	-400	-330.58	-1057.85
3	700	525.92	-531.93
4	-500	-341.51	-873.44
5	1500	931.38	57.94
Method			
IRR	11.48%		
NPV	\$57.94		
IB	\$1057.85		
ORR	11.18%		

\* $k = 10\%$

Note that the final cumulative present value listed in Table 182.2 is necessarily project D's NPV of  $\$57.94$ . Project D's ORR is calculated by substituting into Eq. (182.2) as follows:

$$\left[ \frac{(57.94 + 1057.85) \times (1.10)^5}{1057.85} \right]^{1/5} - 1.0 = .1118$$

In other words, \$1057.85 committed to project D at time 0 will earn an average return of 11.18% per period for five periods.

## 182.5 Scale-Adjusted ORR

---

ORR as defined in Eq. (182.2) should only be used to compare projects of identical scale (i.e., the same investment base). Assuming projects B and C in [Table 182.1](#) are mutually exclusive, they cannot be directly compared, because project C's 11.25% ORR is earned on an investment base of \$2000, whereas project B's 12.48% ORR is earned on an investment base of only \$1000. A project's ORR can be adjusted to any scale by replacing its investment base (IB) in Eq. (182.2) with the desired scale as follows:

$$\text{ORR}_S = \left[ \frac{(S + \text{NPV}) \times (1 + k)^n}{S} \right]^{1/n} - 1.0 \quad (182.3)$$

where  $\text{ORR}_S$  is the project's ORR adjusted to scale  $S$  and  $S$  is the desired scale to which the project's ORR is being adjusted.

These scale adjustments are based on the assumption that differences in project scales can be invested at the firm's opportunity cost  $k$ . Investing at the firm's opportunity cost increases a project's scale but does not affect its NPV. Where two or more competing projects are being compared, the ORRs of all must be adjusted to a common scale (preferably the largest investment base among the projects). ORRs adjusted to a common scale of \$2000 were calculated in [Table 182.1](#) for projects A, B, and C. Those ORRs reveal that the firm should be indifferent in choosing between projects B and C but should prefer either to project A, whose  $\text{ORR}_{2000}$  is 10.63%. These preferences are consistent with the NPV ranking of projects A, B, and C.

## 182.6 Project Life Differences

---

Comparing projects that have different project lives creates certain problems—no matter what decision criterion is being used. Such comparisons generally require an assumption as to what occurs at the end of each project's life—that is, whether the project is or is not replaced with a similar project. Where all competing projects are one-time expenditures with no replacement, their NPVs can be directly compared even if they have different project lives. Such comparison assumes that funds released by any project earn the firm's opportunity cost  $k$  until the end of the longest-lived project. In contrast, the ORRs of competing one-time projects cannot be directly compared if those projects have different lives. Rate criteria such as ORR and IRR measure average performance per period over a project's life, whereas NPV measures cumulative performance over a project's life.

Consider projects E and F in [Table 182.3](#). If we assume that both projects are one-time

expenditures that will not be replaced at the end of their respective lives, the ORRs of projects E and F are not directly comparable. Project E earns an average rate of 13.05% per period for 3 periods, whereas project F earns an average rate of 11.92% per period for 5 periods. The ORR of any project can be calculated over a common life  $z$  periods longer than its project life as follows, by assuming that all funds can be invested at the firm's opportunity cost  $k$  during those  $z$  additional periods:

$$\text{ORR}_{S, n+z} = \left[ \frac{(S + \text{NPV}) \times (1 + k)^{(n+z)}}{S} \right]^{1/(n+z)} - 1.0 \quad (182.4)$$

where  $\text{ORR}_{S, n+z}$  is the project's ORR adjusted to common scale  $S$  and common life  $n + z$ , and  $n + z$  is the common life over which the project's ORR is being calculated. Adjusted to project F's 5-period life, project E's ORR is 11.82% and is less than project F's ORR of 11.92%. Thus, ORRs calculated over a common 5-period life provide the same ranking of projects E and F as is provided by their NPVs.

**Table 182.3** Projects E and F\*

		Project E	Project F
Time	0	−5000	−4000
	1	2500	−1100
	2	2000	2000
	3	2000	2000
	4		2000
	5		1500
Method	IRR	15.02%	13.15%
	NPV	\$428.25	\$452.93
	IB	\$5000.00	\$5000.00
	ORR	13.05%	11.92%
	ORR <sub>5000,5</sub>	11.82%	11.92%

\* $k = 10\%$

Where competing projects are assumed to be replaced at the end of their initial project lives, project rankings for projects having different lives cannot simply be based on the NPVs of the respective projects. Instead, revised projects are generated for each competing project by extending their cash flow streams to some common terminal point. NPVs and ORRs calculated for such revised projects should provide consistent project rankings.

**Example 3/4 Project Analyses.** A firm has been approached by two different manufacturers who want to sell it machines that offer labor savings. The firm will buy one machine at most because both machines being considered perform virtually the same services and either machine has sufficient capacity to handle the firm's entire needs (i.e., mutually exclusive projects). The firm's

cost accounting department has provided management with projected cash flow streams for each of these machines (see Table 182.4) and has suggested a 15% opportunity cost for these machines. When one considers the IRRs and unadjusted ORRs of machines A and B in Table 182.4, it is clear that both are acceptable, since the IRR and the ORR of each exceeds the firm's 15% opportunity cost. It may appear that machine B should be favored because both its IRR and its unadjusted ORR are higher than those of machine A. Note, however, that machines A and B have different investment bases and different lives. Adjusting machine B's ORR to A's larger scale of \$25 000 and to project A's longer 5-period life lowers it from 17.57 to 16.29%. When adjusted to a common scale and a common life, the ORRs of machines A and B provide the same ranking of those two projects as does NPV.

**Table 182.4** Machines A and B \*

	Machine A		Machine B	
	Cash Flow	Cumulative PV	Cash Flow	Cumulative PV
Time				
0	-25 000	-25 000.00	-12 000	-12 000.00
1	7 000	-18 913.04	-4 000	-15 478.26
2	7 000	-13 620.04	10 000	-7 916.82
3	9 000	-7 702.39	9 000	-1 999.18
4	10 000	-1 984.86	6 000	1 431.34
5	7 000	1 495.38		
Method				
IRR	17.41%		19.10%	
NPV	\$1 495.38		\$1 431.34	
IB	\$25 000.00		\$15 478.26	
ORR	16.34%		17.57%	
ORR <sub>25 000,5</sub>	16.34%		16.29%	

\* $k = 15\%$

## 182.7 Conclusion

Rate-of-return criteria can provide correct accept or reject decisions for individual projects and can correctly rank competing projects if used properly. The concept of a rate of return seems easier to understand than NPV. After all, most investments (stocks, bonds, CDs, etc.) are ranked according to their rates of return. The NPV criterion, however, is the "gold standard" and its characteristics of preserving project scale and measuring cumulative performance make it more convenient to use when ranking projects.

Rate-of-return criteria should be viewed as complementing the NPV by providing project performance information in a slightly different form. The IRR provides the average rate earned per period on funds invested in the project itself while they remain so invested. In contrast, the ORR provides the average rate earned per period on the project's investment base over the entire life of the project, assuming that funds earn the firm's opportunity cost when not invested in the project

itself.

## Defining Terms

**Internal rate of return:** The average rate earned per period on funds invested in the project itself.

**Investment base:** The time 0 value of the funds that must be provided to (invested in) the project during its life.

**Net present value:** The expected increase in a firm's value if and when it implements the project.

**Opportunity cost:** The rate of return the firm believes it can earn on projects of similar risk. Also referred to as the *minimum required return*, the *discount rate*, or the project's *hurdle rate*.

**Overall rate of return:** The average rate earned per period on the project's investment base over the life of the project.

Practical engineering and management requires choices among competing alternatives. Which boiler should be used in a plant? Which computer should be purchased for a design office? Which financing scheme would be most desirable for a new facility? These are practical questions that arise in the ordinary course of engineering design, organizational management, and even personal finances. This chapter is intended to present methods for choosing the best among distinct alternatives.

### 183.1 Problem Statement for Project Selection

---

The economic project selection problem is to identify the best from a set of possible alternatives. Selection is made on the basis of a systematic analysis of expected revenues and costs over time for each project alternative.

Project selection falls into three general classes of problems. Accept-reject problems (also known as a *determination of feasibility*) require an assessment of whether or not an investment is worthwhile. For example, the hiring of an additional engineer in a design office is an accept-reject decision. Selection of the best project from a set of mutually exclusive projects is required when there are several competing projects or options and only one project can be built or purchased. For example, a town building a new sewage treatment plant may consider three different configurations, but only one configuration will be built. Finally, capital budgeting problems are concerned with the selection of a set of projects when there is a budget constraint and many, not necessarily competing, options. For example, a state highway agency will consider many different

highway rehabilitation projects for a particular year, but generally the budget is insufficient to allow all to be undertaken, although they may all be feasible.

## 183.2 Steps in Carrying Out Project Selection

---

A systematic approach for economic evaluation of projects includes the following major steps [Hendrickson, 1989]:

1. Generate a set of project or purchase **alternatives** for consideration. Each alternative represents a distinct component or combination of components constituting a purchase or project decision. We shall denote project alternatives by the subscript  $x$ , where  $x = 1, 2, \dots$  refers to projects 1, 2, and so on.
2. Establish a **planning horizon** for economic analysis. The planning horizon is the set of future periods used in the economic analysis. It could be very short or long. The planning horizon may be set by organizational policy (e.g., 5 years for new computers or 50 years for new buildings), by the expected economic life of the alternatives, or by the period over which reasonable forecasts of operating conditions may be made. The planning horizon is divided into discrete periods—usually years, but sometimes shorter units. We shall denote the planning horizon as a set of  $t = 0, 1, 2, 3, \dots, n$ , where  $t$  indicates different periods, with  $t = 0$  being the present,  $t = 1$  the first period, and  $t = n$  representing the end of the planning horizon.
3. Estimate the **cash flow profile** for each alternative. The cash flow profile should include the revenues and costs for the alternative being considered during each period in the planning horizon. For public projects, revenues may be replaced by estimates of benefits for the public as a whole. In some cases revenues may be assumed to be constant for all alternatives, so only costs in each period are estimated. Cash flow profiles should be specific to each alternative, so the costs avoided by not selecting one alternative (say,  $x = 5$ ) are not included in the cash flow profile of the alternatives ( $x = 1, 2$ , and so on). Revenues for an alternative  $x$  in period  $t$  are denoted  $B(t, x)$ , and costs are denoted  $C(t, x)$ . Revenues and costs should initially be in **base-year** or constant dollars. Base-year dollars do not change with inflation or deflation.

For tax-exempt organizations and government agencies, there is no need to speculate on inflation if the cash flows are expressed in terms of base-year dollars and a MARR without an inflation component is used in computing the net present value. For private corporations that pay taxes on the basis of then-current dollars, some modification should be made to reflect the projected inflation rates when considering depreciation and corporate taxes.

4. Specify the **minimum attractive rate of return (MARR)** for discounting. Revenues and costs incurred at various times in the future are generally not valued equally to revenues and costs occurring in the present. After all, money received in the present can be invested to obtain interest income over time. The MARR represents the trade-off between monetary amounts in different periods and does not include inflation. The MARR is usually expressed as a percentage change per year, so that the MARR for many public projects may be stated as

10%. The value of MARR is usually set for an entire organization based upon the opportunity cost of investing funds internally rather than externally in the financial markets. For public projects the value of MARR is a political decision, so MARR is often called the *social rate of discount* in such cases. The equivalent value of a dollar in a following period is calculated as  $(1 + \text{MARR})$ , and the equivalent value two periods in the future is  $(1 + \text{MARR})^2$ . In general, if you have  $Y$  dollars in the present [denoted  $Y(0)$ ], then the future value in time  $t$  [denoted  $Y(t)$ ] is

$$Y(t) = Y(0)(1 + \text{MARR})^t \quad (183.1)$$

or the present value,  $Y(0)$ , of a future dollar amount  $Y(t)$  is

$$Y(0) = Y(t)/(1 + \text{MARR})^t \quad (183.2)$$

5. Establish the criterion for accepting or rejecting an alternative and for selecting the best among a group of mutually exclusive alternatives. The most widely used and simplest criterion is the **net present value** criterion. Projects with a positive net present value are acceptable. Only one from a group of mutually exclusive alternatives can be chosen. For example, the alternatives might be alternative boilers for a building or alternative airport configurations. From a set of mutually exclusive alternatives, the alternative with the highest net present value is best. The next section details the calculation steps for the net present value and also some other criterion for selection.
6. Perform sensitivity and uncertainty analysis. Calculation of net present values assumes that cash flow profiles and the value of MARR are reasonably accurate. In many cases assumptions are made in developing cash flow profile forecasts. Sensitivity analysis can be performed by testing a variety of such assumptions, such as different values of MARR, to see how alternative selection might change. Formally treating cash flow profiles and MARR values as stochastic variables can be done with probabilistic and statistical methods.

## 183.3 Selection Criteria

---

### Net Present Value

Calculation of net present values to select projects is commonly performed on electronic calculators, on commercial spreadsheet software, or by hand. The easiest calculation approach is to compute the net revenue in each period for each alternative, denoted  $A(t, x)$ :

$$A(t, x) = B(t, x) - C(t, x) \quad (183.3)$$

where  $A(t, x)$  may be positive or negative in any period. Then, the net present value of the alternative,  $\text{NPV}(x)$ , is calculated as the sum over the entire planning horizon of the discounted

values of  $A(t, x)$ :

$$\text{NPV}(x) = \sum_{t=0}^n A(t, x)/(1 + \text{MARR})^t \quad (183.4)$$

## Other Methods

Several other criteria may be used to select projects. Other discounted flow methods include **net future value** [denoted  $\text{NFV}(x)$ ] and **equivalent uniform annual value** [denoted  $\text{EUAV}(x)$ ]. It can be shown [Au, 1992] that these criteria are equivalent where

$$\text{NFV}(x) = \text{NPV}(x)(1 + \text{MARR})^n \quad (183.5)$$

$$\text{EUAV}(x) = \frac{\text{NPV}(x)(1 + \text{MARR})^n}{[(1 + \text{MARR})^n - 1]} \quad (183.6)$$

The net future value is the equivalent value of the project at the end of the planning horizon. The equivalent uniform annual value is the equivalent series in each year of the planning horizon.

Alternatively, benefit-to-cost ratio (the ratio of the discounted benefits to discounted costs) and the internal rate of return [the equivalent MARR at which  $\text{NPV}(x) = 0$ ] are merit measures, each of which may be used to formulate a decision. For accept-reject decisions, the benefit-to-cost ratio must be greater than one and the internal rate of return greater than the MARR. However, these measures must be used in connection with incremental analyses of alternatives to provide consistent results for selecting among mutually exclusive alternatives [see, for instance, Au (1992)].

Similarly, the payback period provides an indication of the time it takes to recoup an investment but does not indicate the best project in terms of expected net revenues.

## 183.4 Applications

To illustrate the application of these techniques and the calculations involved, two examples are presented.

**Example 183.14 Alternative Bridge Designs.** A state highway agency is planning to build a new bridge and is considering two distinct configurations. The initial costs and annual costs and benefits for each bridge are shown in the following table. The bridges are each expected to last 30 years.

	Alternative 1	Alternative 2
Initial cost	\$15 000 000	\$25 000 000
Annual maintenance and operating costs	\$15 000	\$10 000
Annual benefits	\$1 200 000	\$1 900 000
Annual benefits less costs	\$1 185 000	\$1 890 000

**Solution.** The net present values for a MARR of 5% are given as follows:

$$\begin{aligned}\text{NPV}(1) &= (-15\,000\,000) + (1\,185\,000)/(1 + 0.05) + (1\,185\,000)/(1 + 0.05)^2 \\ &\quad + (1\,185\,000)/(1 + 0.05)^3 + \cdots + (1\,185\,000)/(1 + 0.05)^{30} \\ &= \$3\,216\,354\end{aligned}$$

$$\begin{aligned}\text{NPV}(2) &= (-15\,000\,000) + (1\,890\,000)/(1 + 0.05) + (1\,890\,000)/(1 + 0.05)^2 \\ &\quad + (1\,890\,000)/(1 + 0.05)^3 + \cdots + (1\,890\,000)/(1 + 0.05)^{30} \\ &= \$4\,053\,932\end{aligned}$$

Therefore, the department of transportation should select the second alternative, which has the largest net present value. Both alternatives are acceptable since their net present values are positive, but the second alternative has a higher net benefit.

**Example 183.2% Equipment Purchase.** Consider two alternative methods for sealing pavement cracks [McNeil, 1992]. The first method is a manual method; the second is an automated method using a specialized equipment system. Which method should be used? We shall solve this problem by analyzing whether the new automated method has revenues and benefits in excess of the existing manual method.

**Solution.** Following the steps outlined earlier, the problem is solved as follows:

1. The alternatives for consideration are (1) the existing manual method, and (2) the automated method. The alternatives are mutually exclusive because cracks can only be sealed using either the existing method or the new method.
2. The planning horizon is assumed to be 6 years to coincide with the expected life of the automated equipment.
3. The cash flow profile for alternative 2 is given in the following table:

System acquisition costs	\$100 000
Annual maintenance and operating costs	\$10 000
Annual labor savings	\$36 000
Annual savings over costs	\$26 000

The values are estimated using engineering judgment and historical cost experience. We assume that the productivity and revenues for both alternatives are the same and treat labor savings as additional benefits for alternative 2. Therefore, only the net present value for alternative 2, which represents the result of introducing the automated method, need be computed.

4. The MARR is assumed to be 5%. The net present value is computed as follows:

$$\begin{aligned}
\text{NPV}(2) &= 100\,000 + (26\,000)/(1 + 0.05) \\
&\quad + (26\,000)/(1 + 0.05)^2 + \cdots + (26\,000)/(1 + 0.05)^5 \quad (183.7) \\
&= \$12\,566
\end{aligned}$$

5. Using the criterion  $\text{NPV}(2) > 0$ , alternative 2 is selected.

6. To determine the sensitivity of the result to some of the assumptions, consider [Table 183.1](#). The table indicates that additional investment in the automated method is justifiable at the MARR of 5% if the acquisition costs decrease or the labor savings increase. However, if the MARR increases to 10% or the acquisition costs increase, then the investment becomes uneconomical.

**Table 183.1** Energy Price Escalation Rates

Acquisition Cost (\$)	Labor Saving (\$)	Maintenance and Operation (\$)	MARR		
			0.05	0.01	0.15
50 000	36 000	10 000	\$62 566	\$48 560	\$37 156
100 000	36 000	10 000	\$12 566	(\$1 440)	(\$12 844)
150 000	36 000	10 000	(\$37 434)	(\$51 440)	(\$62 844)
50 000	45 000	10 000	\$101 532	\$82 678	\$67 325
100 000	45 000	10 000	\$51 532	\$32 678	\$17 325
150 000	45 000	10 000	\$1 532	(\$17 322)	(\$32 675)

This example illustrates the use of the net present value criteria for an incremental analysis, which assumes that the benefits are constant for both alternatives and examines incremental costs for one project over another.

## 183.5 Conclusion

This chapter has presented the basic steps for assessing economic feasibility and selecting the best project from a set of mutually exclusive projects, with net present value as a criterion for making the selection.

### Defining Terms

**Alternatives:** A distinct option for a purchase or project decision.

**Base year:** The year used as the baseline of price measurement of an investment project.

**Cash flow profile:** Revenues and costs for each period in the planning horizon.

**Equivalent uniform annual value:** Series of cash flows with a discounted value equivalent to the net present value.

**Minimum attractive rate of return (MARR):** Percentage change representing the time value of money.

**Net future value:** Algebraic sum of the computed cash flows at the end of the planning horizon.

**Net present value:** Algebraic sum of the discounted cash flows over the life of an investment project to the present.

**Planning horizon:** Set of time periods from the beginning to the end of the project; used for economic analysis.

**Tung Au**

*Carnegie Mellon University*

The government levies taxes on corporations and individuals to meet its cost of operations. Regulations on depreciation allowances are part of the taxation policy. The tax laws promulgated by the federal government profoundly influence capital investments undertaken by private corporations. Economic valuation of the after-tax cash flows of an investment project based on projected tax rates and inflation effects provides a rational basis for accepting or rejecting investment projects.

### 184.1 Depreciation as Tax Deduction

---

**Depreciation** refers to the decline in value of physical assets over their estimated useful lives. In the context of tax liability, **depreciation allowance** refers to the amount allowed as a deduction in computing taxable income, and **depreciable life** refers to the estimated useful life over which depreciation allowances are computed. Historically, an asset could not be depreciated below a reasonable salvage value. Thus, depreciation allowance is a systematic allocation of the cost of a physical asset between the time it is acquired and the time it is disposed of.

The methods of computing depreciation and the estimated useful lives for various classes of physical assets are specified by government regulations as a part of the tax code, which is subject to periodic revisions. Different methods of computing depreciation lead to different annual depreciation allowances and hence have different effects on taxable income and the taxes paid.

Let  $P$  be the historical cost of an asset,  $S$  its estimated salvage value, and  $N$  the depreciable life in

years. Let  $D_t$  denote the depreciable allowance in year  $t$ , and  $T_t$  denote the accumulated depreciation up to and including year  $t$ . Then for  $t = 1, 2, \dots, N$ ,

$$T_t = D_1 + D_2 + \dots + D_t \quad (184.1)$$

An asset's book value  $B_t$  is simply its historical cost less any accumulated depreciation. Then

$$B_t = P - T_t \quad (184.2)$$

or

$$B_t = B_{t-1} - D_t \quad (184.3)$$

Among the depreciation methods acceptable under the tax regulations, the straight-line method is the simplest. Using this method, the uniform annual allowance in each year is

$$D_t = (P - S)/N \quad (184.4)$$

Other acceptable methods, known as *accelerated depreciation methods*, yield higher depreciation allowances in the earlier years of an asset and less in the later years than those obtained by the straight-line method. Examples of such methods are sum-of-the-years'-digits depreciation and double-declining-balance depreciation, which are treated extensively elsewhere [Au and Au, 1992].

Under the current IRS regulations on depreciation, known as the Modified Accelerated Cost Reduction System, the estimated useful life of an asset is determined by its characteristics that fit one of the eight arbitrarily specified categories. Furthermore, the salvage value  $S$  for all categories is assumed to be zero, whereas all equipment with life of ten years or less is assumed to be purchased at mid-year.

## 184.2 Tax Laws and Tax Planning

---

Capital projects are long-lived physical assets for which the promulgation and revisions of tax laws may affect the tax liability. For the purpose of planning and evaluating capital projects, it is important to understand the underlying principles, including the adjustments for the transition period after each revision and for multiyear "carry-back" or "carry-forward" of profits and losses.

The federal income tax is important to business operations because profits are taxed annually at substantial rates on a graduated basis. Except for small businesses, the corporate taxes on ordinary income may be estimated with sufficient accuracy by using the marginal tax rate. **Capital gain**, which represents the difference between the sale price and the book value of an asset, is taxed at a rate lower than on ordinary income if it is held longer than a period specified by tax laws.

Some state and/or local governments also levy income taxes on corporations. Generally, such taxes are deductible for federal income tax to avoid double taxation. The computation of income taxes can be simplified by using a combined tax rate to cover the federal, state, and local income taxes.

Tax planning is an important element of private capital investment analysis because the economic feasibility of a project is affected by the taxation of corporate profits. In making estimates of tax liability, several factors deserve attention: (1) number of years for retaining the asset, (2) depreciation method used, (3) method of financing, including purchase versus lease, (4) capital gain upon the sale of the asset, and (5) effects of inflation. Appropriate assumptions should be made to reflect these factors realistically.

### 184.3 Decision Criteria for Project Selection

---

The economic evaluation of an investment project is based on the merit of the **net present value**, which is the algebraic sum of the discounted net cash flows over the life of the project to the present. The discount rate is the minimum attractive rate of return specified by the corporation.

The evaluation of proposed investment projects is based on the net present value criteria, which specify the following: (1) an independent project should be accepted if the NPV is positive and rejected otherwise; and (2) among all acceptable projects that are mutually exclusive, the one with the highest positive NPV should be selected.

A more general treatment of the net present value decision criteria for economic evaluation of investment projects may include effects of different reinvestment assumptions [Beaves, 1993] and different scales of investment [Shull, 1992].

### 184.4 Inflation Consideration

---

The consideration of the effects of inflation on economic evaluation of a capital project is necessary because taxes are based on then-current dollars in future years. The year in which the useful life of a project begins is usually used as the baseline of price measurement and is referred to as the **base year**. A **price index** is the ratio of the price of a predefined package of goods and service at a given year to the price of the same package in the base year. The common price indices used to measure inflation include the consumer price index, published by the Department of Labor, and the gross domestic product price deflator, compiled by the Department of Commerce.

For the purpose of economic evaluation, it is generally sufficient to project the future inflation trend by using an average annual inflation rate  $j$ . Let  $A_t$  be the cash flow in year  $t$ , expressed in terms of base-year (year 0) dollars, and  $A'_t$  be the cash flow in year  $t$ , expressed in terms of then-current dollars. Then

$$A'_t = A_t(1 + j)^t \quad (184.5)$$

$$A_t = A'_t(1 + j)^{-t} \quad (184.6)$$

In the economic evaluation of investment proposals in an inflationary environment, two approaches may be used to offset the effects of inflation. Each approach leads to the same result if the discount rate  $i$ , excluding inflation, and the rate  $i'$ , including inflation, are related as follows:

$$i' = (1 + i)(1 + j) - 1 = i + j + ij \quad (184.7)$$

$$i = (i' - j)/(1 + j) \quad (184.8)$$

The net present value (NPV) of an investment project over a planning horizon of  $n$  years can be obtained by using the constant price approach as follows:

$$NPV = \sum_{t=0}^n A_t(1 + i)^{-t} \quad (184.9)$$

Similarly, the NPV obtained by using the then-current price approach is

$$NPV = \sum_{t=0}^n A'_t(1 + i')^{-t} \quad (184.10)$$

In some situations the prices of certain key items affecting the estimates of future incomes and/or costs are expected to escalate faster than the general inflation. For such cases the differential inflation for those items can be included in the estimation of the cash flows for the project.

## 184.5 After-Tax Cash Flows

---

The economic performance of a corporation over time is measured by the net cash flows after tax. Consequently, after-tax cash flows are needed for economic evaluation of an investment project. Since interests on debts are tax deductible according to the federal tax laws, the method of financing an investment project could affect the net profits. Although the projected net cash flows over the years must be based on then-current dollars for computing taxes, the depreciation allowances over those years are not indexed for inflation under the current tax laws.

It is possible to separate the cash flows of a project into an operating component and a financing component for the purpose of evaluation. Such a separation will provide a better insight to the tax advantage of borrowing to finance a project, and the combined effect of the two is consistent with the computation based on a single combined net cash flow. The following notations are introduced to denote various items in year  $t$  over a planning horizon of  $n$  years:

$A_t$  = net cash flow of operation (excluding financing cost) before tax

$A_t$  = net cash flow of financing before tax

$A_t = A_t + A_t =$  combined net cash flow before tax  
 $Y_t =$  net cash flow of operation (excluding financing cost) after tax  
 $Y_t =$  net cash flow of financing after tax  
 $Y_t = Y_t + Y_t =$  combined net cash flow after tax  
 $D_t =$  annual depreciation allowance  
 $I_t =$  annual interest on the unpaid balance of a loan  
 $Q_t =$  annual payment to reduce the unpaid balance of a loan  
 $W_t =$  annual taxable income  
 $X_t =$  annual marginal income tax rate  
 $K_t =$  annual income tax

Thus, for operation in year  $t = 0, 1, 2, \dots, n$ ,

$$W_t = A_t - D_t \quad (184.11)$$

$$K_t = X_t W_t \quad (184.12)$$

$$Y_t = A_t - X_t(A_t - D_t) \quad (184.13)$$

For financing in year  $t = 0, 1, 2, \dots, n$ ,

$$I_t = Q_t - A_t \quad (184.14)$$

$$Y_t = A_t + X_t I_t \quad (184.15)$$

where the term  $X_t I_t$  is referred to as the **tax shield** because it represents a gain from debt financing due to the deductibility of interests in computing the income tax.

Alternately, the combined net cash flows after tax may be obtained directly by noting that both depreciation allowance and interest are tax deductible. Then,

$$W_t = A_t - D_t - I_t \quad (184.16)$$

$$Y_t = A_t - X_t(A_t - D_t - I_t) \quad (184.17)$$

It can be verified that Eq. (184.17) can also be obtained by adding Eqs. (184.13) and (184.15), while noting  $A_t = A_t + A_t$  and  $Y_t = Y_t + Y_t$ .

## 184.6 Evaluation of After-Tax Cash Flows

---

For private corporations the decision to invest in a capital project may have side effects on the financial decisions of the firm, such as taking out loans or issuing new stocks. These financial decisions will influence the overall equity-debt mix of the entire corporation, depending on the size of the project and the risk involved.

Traditionally, many firms have used an adjusted cost of capital, which reflects the opportunity

cost of capital and the financing side effects, including tax shields. Thus only the net cash from operation  $Y_t$  obtained by Eq. (184.13) is used when the net present value is computed. The after-tax net cash flows of a proposed project are discounted by substituting  $Y_t$  for  $A_t$  in Eq. (184.9), using after-tax adjusted cost of capital of the corporation as the discount rate. If inflation is anticipated,  $Y'_t$  can first be obtained in then-current dollars and then substituted into Eq. (184.10). The selection of the project will be based on the NPV thus obtained without further consideration of tax shields, even if debt financing is involved. This approach, which is based on the adjusted cost of capital for discounting, is adequate for small projects such as equipment purchase.

In recent years another approach, which separates the investment and financial decisions of a firm, is sometimes used for evaluation of large capital projects. In this approach the net cash flows of operation are discounted at a risk-adjusted rate reflecting the risk for the class of assets representing the proposed project, whereas tax shields and other financial side effects are discounted at a risk-free rate corresponding to the yield of government bonds. An adjusted net present value reflecting the combined effects of both decisions is then used as the basis for project selection. The detailed discussion of this approach may be found elsewhere [Brealey and Myers, 1988].

## 184.7 Effects of Various Factors

---

Various depreciation methods will produce different effects on the after-tax cash flows of an investment. Since the accelerated depreciation methods generate larger depreciation allowances during the early years, the net present value of the after-tax cash flows using one of the accelerated depreciation methods is expected to be more favorable than that obtained by using the straight-line method.

If a firm lacks the necessary funds to acquire a physical asset that is deemed desirable for operation, it can lease the asset by entering into a contract with another party, which will legally obligate the firm to make payments for a well-defined period of time. The payments for leasing are expenses that can be deducted in full from the gross revenue in computing taxable income. The purchase-or-lease options can be compared after their respective net present values are computed.

When an asset is held for more than a required holding period under tax laws, the capital gain is regarded as long-term capital gain and is taxed at a lower rate. In a period of inflation the sale price of an asset in then-current dollars increases, but the book value is not allowed to be indexed to reflect the inflation. Consequently, capital gain tax increases with the surge in sale price resulting from inflation.

**Example 184.1.** A heavy-duty truck is purchased at \$25 000 in February. This truck is expected to generate a before-tax uniform annual revenue of \$7000 over the next six years, with a salvage value of \$3000 at the end of six years. According to the current IRS regulations, this truck is assigned an estimated useful life of five years with no salvage value. The straight-line depreciation method is used to compute the annual depreciation allowance. The combined federal and state income tax rate is 38%. Assuming no inflation, the after-tax discount rate of 8%, based on the

adjusted cost of capital of the corporation, is used. Determine whether this investment proposal should be accepted.

**Solution.** Using Eq. (184.4), the annual depreciation allowance  $D_t$  is found to be 5000 per year, since a useful life of five years is specified and the salvage value is zero, according to the current IRS regulations. Following the mid-year purchase assumption, the actual depreciation allowances for years one through six are as shown in the following table. The actual revenues over six years are used in the analysis.

$t$	$A_t$	$D_t$	$A_t - D_t$	$K_t$	$Y_t$
0	-25 000	—	—	—	-25 000
1	7 000	2500	2500	1710	5 290
2-5	7 000	5000	2000	760	6 240
6	7 000	2500	4500	1710	5 290

Using the adjusted cost of capital approach, the net present value of the after-tax net cash flows discounted at 8% is obtained by substituting  $Y_t$  for  $A_t$  in Eq. (184.9),

$$\begin{aligned} \text{NPV} = & -25\,000 + (6240)(P | U, 8\%, 5) - (6240 - 5290)(P | F, 8\%, 1) \\ & + (5290)(P | F, 8\%, 5) = 2369 \end{aligned}$$

in which  $(P | U, 8\%, 5)$  is the discount factor to present at 8% for a uniform series over 5 years, and  $(P | F, 8\%, 1)$  and  $(P | F, 8\%, 5)$  are discount factors to present at 8% for a future sum at the end of 1 year and 5 years, respectively. Since  $\text{NPV} = 2369$  is positive, the proposed investment should be accepted.

**Example 184.2.** Consider a proposal for the purchase of a computer workstation that costs \$20 000 and has no salvage value at disposal after four years. This investment is expected to generate a before-tax uniform annual revenue of \$7000 in base-year dollars over the next four years. An average annual inflation rate of 5% is assumed. The straight-line depreciation method is used to compute the annual depreciation allowance. The combined federal and state income tax rate is 38%. Based on the adjusted cost of capital of the corporation, the after-tax discount rate, including inflation, is 10%. Determine whether this investment proposal should be accepted.

**Solution.** To simplify the calculation, the assumption of mid-year purchase is ignored. Using Eq. (184.4), the annual depreciation allowance  $D_t$  is found to be \$5000 for  $t = 1$  to 4. This annual depreciation allowance of \$5000 will not be indexed for inflation, according to the IRS regulations.

The annual before-tax revenue of \$7000 in base-year dollars must be expressed in then-current dollars before computing the income taxes. From Eq. (184.5),

$$A'_t = (7000)(1 + 0.05)^t$$

where  $t = 1$  to 4 refers to each of the next four years. The after-tax cash flow  $Y'_t$  for each year can be computed by Eq. (184.13). The step-by-step tabulation of the computation for each year is shown in the following table.

$t$	$A_t$	$A'_t$	$D_t$	$A'_t - D_t$	$K_t$	$Y'_t$
0	-20 000	-20 000	—	—	—	-20 000
1	7 000	7 350	5999	2359	893	6 457
2	7 000	7 718	5000	2718	1033	6 685
3	7 000	8 013	5000	3103	1179	6 924
4	7 000	8 509	5000	3509	1333	7 176

Using the adjusted cost of capital approach, the net present value of the after-tax cash flows discounted at  $i' = 10\%$ , including inflation, can be obtained by substituting the value of  $Y'_t$  for  $A'_t$  in Eq. (184.10) as follows:

$$\begin{aligned} \text{NPV} &= -20\,000 + (6457)(1.1)^{-1} + (6685)(1.1)^{-2} + (6924)(1.1)^{-3} + (7176)(1.1)^{-4} \\ &= 1498 \end{aligned}$$

Since  $\text{NPV} = \$1498$  is positive, the investment proposal should be accepted.

**Example 184.3.** A developer bought a plot of land for \$100 000 and spent \$1.6 million to construct an apartment building on the site for a total price of \$1.7 million. The before-tax annual rental income after the deduction of maintenance expenses is expected to be \$300 000 in the next six years, assuming no inflation. The developer plans to sell this building at the end of six years when the property is expected to appreciate to \$2.1 million, including land. The entire cost of construction can be depreciated over 32 years based on the straight-line depreciation method, whereas the original cost of land may be treated as the salvage value at the end. The tax rates are 34% for ordinary income and 28% for capital gain, respectively. Based on the adjusted cost of capital, the developer specifies an after-tax discount rate of 10%.

**Solution.** Using Eq. (184.4), the annual depreciation allowance  $D_t$  over 32 years is found to be 50 000. Noting that  $P = 1\,700\,000$  and  $T_t = (6)(50\,000) = 300\,000$ , the book value of the property after six years is found from Eq. (184.2) to be \$1.4 million.

Ignoring the assumption of mid-year purchase to simplify the calculation and assuming no inflation, the after-tax annual net income in the next six years is given by Eq. (184.13):

$$Y_t = 300\,000 - (34\%)(300\,000 - 50\,000) = 215\,000$$

The capital gain tax for the property at the end of 6 years is

$$(28\%)(2\,100\,000 - 1\,400\,000) = 196\,000$$

Using the adjusted cost of capital approach, the net present value of after-tax net cash flows in

the next six years, including the capital gain tax paid at the end of six years discounted at 10%, is

$$\begin{aligned}\text{NPV} &= -1\,700\,000 + (215\,000)(P | U, 10\%, 6) \\ &\quad + (2\,100\,000 - 196\,000)(P | F, 10\%, 6) \\ &= 311\,198\end{aligned}$$

in which  $(P | U, 10\%, 6)$  is the discount factor to present at 10% for a uniform series over six years, and  $(P | F, 10\%, 6)$  is the discount factor to present at 10% for a future sum at the end of six years. Since  $\text{NPV} = \$311\,198$  is positive, the proposed investment should be accepted.

## Defining Terms

**Base year:** The year used as the baseline of price measurement of an investment project.

**Capital gain:** Difference between the sale price and the book value of an asset.

**Depreciable life:** Estimated useful life over which depreciation allowances are computed.

**Depreciation:** Decline in value of physical assets over their estimated useful lives.

**Depreciation allowance:** Amount of depreciation allowed in a systematic allocation of the cost of a physical asset between the time it is acquired and the time it is disposed of.

**Net present value:** Algebraic sum of the discounted cash flows over the life of an investment project to the present.

**Price index:** Ratio of the price of a predefined package of goods and service at a given year to the price of the same package in the base year.

**Tax shield:** Gain from debt financing due to deductibility of interests in computing the income tax.

In other chapters a firm's investment decision has been discussed in terms of capital budgeting. This chapter focuses on the other major decision that a firm must face: where to obtain the funds to invest in these capital projects. The decision of where to raise the money is called the financing decision. The market for funds is divided into the money market and the capital market. The money market includes short-term debt securities, that is, securities that will mature in one year or less. The capital market is the market for longer-term borrowings, that is, sources of cash with a time horizon of more than one year. The capital market is further subdivided into an intermediate capital market, which includes debt securities with a maturity of more than one but less than ten years, and a long-term capital market, which includes debt securities which generally have a maturity of more than ten years. Financing activities for capital projects rarely utilize money market funds.

The capital market also encompasses the market for equity securities. These sources of funds include the issuance of both preferred stock and common stock. They have the longest time horizon since these securities are normally issued for the life of the corporation. Thus they may be thought of as sources of financing with an infinite time horizon.

This article will deal with the major sources and forms of capital market funds. In addition, leasing will be discussed. Leasing is a specific type of economic transaction that blends the acquisition of an asset (an investment decision) with a long-term loan commitment (a financing decision). Under the right conditions, leasing can represent a most attractive approach to the financing process for a firm.

### 185.1 Debt Financing

---

There are three primary sources of intermediate and long-term debt financing: term loans,

mortgage loans, and bonds.

## Term Loans

A **term loan** is simply a loan that is paid off over some number of years called the term of the loan. Term loans may or may not be secured by the assets of the firm. These loans are usually negotiated with commercial banks, insurance companies, or some other financial institution. They can generally be negotiated fairly quickly and at a low administrative cost. The amount borrowed (principal) and the interest are paid off in installments over the life of the loan. The rate of interest on the term loan can be fixed over the life of the loan, but usually it is a variable interest rate that is linked to the prime rate. Thus if the rate of interest for a term loan is set at "2% over the prime rate," the borrower may pay 8% when the prime rate is 6% in the first year, and 9% in the second year when the prime rate is 7%. Variable-rate loans of this type can include a "collar," which sets upper and lower limits on the interest rate that can be charged, or a "cap," which sets an upper limit only. The prime rate of interest is the rate charged on short-term business loans to financially sound companies. Term loans often carry restrictive provisions or constraints on the financial activities of the borrower, such as a dividend restriction.

## Mortgage Loans

Mortgage loans are essentially term loans secured by the real estate that was purchased with the cash proceeds from the loan. They infrequently extend past a time period of 20 years and may be repaid only over 5 years.

## Bonds

**Bonds** are intermediate to long-term debt agreements issued by corporations, governments, or other organizations, generally in units of \$1000 principal value per bond. A bond represents two commitments on the part of the issuing organization: the promise to pay the stated interest rate periodically and the commitment to repay the \$1000 principal when the bond matures. Most bonds pay interest semiannually at one-half the annual stated or coupon rate of interest. The term *coupon rate* refers to the fact that bonds often come with coupons that may be detached and redeemed for each interest payment.

A company that floats a bond issue may have the bonds sold directly to the public by placing the bond issue with an investment banker. A bond issue can also be privately placed with a financial institution such as a commercial bank, insurance company, corporate pension fund, or university endowment fund. The contract between the issuer and the lender is called the bond indenture. If the bond is publicly marketed, a trustee is named to ensure compliance with the bond indenture. In most cases the trustee is a commercial bank or an investment banker. In a private placement, the purchasing institution normally acts as its own trustee.

Bonds are issued in a wide variety of circumstances. A debenture is an unsecured bond that is backed by the full faith and credit of the issuer. No specific assets are pledged as collateral. In the event of default, debenture holders become general creditors of the issuer. A mortgage bond, like a

mortgage loan, is collateralized by a mortgage on some type of asset, such as land or a building.

Convertible bonds are bonds that may be converted into shares of common stock in a pre-determined conversion rate. The decision to convert the bond to common stock is at the option of the bondholder. The conversion feature is attractive to investors and therefore lowers the cost of borrowing.

Most bond issues include a call feature among the provisions. This feature gives the issuer a chance to buy back the bonds at a stated price prior to maturity. Callable bonds give the issuer flexibility in financing its activities. The call feature favors the borrower and therefore increases the effective cost of borrowing.

A sinking fund requirement establishes a procedure for the orderly retirement of a bond issue over its life. This provision requires the periodic repurchase of a stated percentage of the outstanding bonds. The issuing company can accomplish this through purchases of their bonds in the open market or through the use of the call provision previously described.

## 185.2 Equity Financing

---

Equity financing utilizes a corporation's ability to sell ownership interest in the organization through the sale of capital stock in the corporation. This stock can be issued either as preferred stock or as common stock. While a corporation can choose to issue preferred stock, it must issue common stock as a representation of the individual ownership interest of the investors.

### Preferred Stock

**Preferred stock** is legally an equity security that represents an ownership interest in a corporation. The term *preferred* arises from the fact that preferred stock has two important preferences over common stock: preference as to payment of dividends and preference as to stockholders' claims on the assets of the business in the event of bankruptcy.

Preferred stock is often characterized as a hybrid security that possesses some of the features of bonds and some of the features of common stock. Preferred dividends are fixed in amount similar to bond interest, and must be paid before common dividends are paid. Like bondholders, preferred stockholders do not participate in the growth of corporate earnings and collect only the dividends that are stated on the stock certificate. Like common stockholders, each dividend payment must be voted on and approved by the board of directors of the corporation. Most preferred stock issuances are cumulative, meaning that missed dividends accumulate as "dividends in arrears," which must be paid before any common dividends can be paid. Timely payment of preferred dividends is very important to the corporation. Corporations with preferred dividends in arrears find it very difficult to raise other forms of capital. Therefore, payment of preferred dividends is almost as important as timely payment of bond interest to the corporation. Preferred stock can also be convertible and callable, as discussed earlier in conjunction with bonds.

### Common Stock

The common stockholders are the owners of the corporation, as evidenced by the voting rights that

are normally associated with **common stock**. Each share of common stock normally has one vote in electing the corporation's board of directors. The board is the ultimate corporate authority and is the group to which the president of the corporation reports. The board selects the president and approves the appointment of all the corporate officers. The board members are responsible to the stockholders, and the stockholders have the authority to elect a new board if their performance is deemed unsatisfactory.

Common stock is often referred to as the residual equity of the corporation. Money paid to the corporation for common stock does not have to be repaid, and dividends on common stock are paid only when approved by the board of directors. Common dividends are never in arrears, and common stockholders never have a claim to any specified dividend level. If a corporation prospers and grows, the board will normally vote to increase the dividend level to reflect this growth. As dividends grow, the value of the stock increases, and the stockholders also benefit from capital gains which accrue from the increased value. Of course, all of this can also work in reverse if the corporation does not prosper. The shareholders could ultimately lose their investment if the corporation goes bankrupt.

Corporations sometimes issue two classes of common stock, one of which does not include any voting rights. Thus, voting rights are retained by one class of common stock, and the other class will not have any voting rights but will have the ability to participate in earnings growth. This will allow one group of owners to retain voting control while allowing another group to participate in earnings and dividends but with no control. This is a way to raise additional equity capital without losing control of the corporation. Large publicly held corporations rarely have multiple classes of common stock.

## 185.3 Leasing

---

A **lease** can be defined as a contractual relationship in which the owner of the property or asset (lessor) conveys to a business or person (lessee) the right to use the property or asset for a specified period of time in exchange for a series of payments. Thus in a lease contract the lessee is able to use the leased assets without assuming ownership. Leasing has become a very popular way for many businesses to acquire the necessary resources to run their operations. The leasing event is a hybrid transaction which combines the acquisition of necessary resources with a commitment to finance the acquisition. In general, two types of leases are offered in the market today: operating leases and financial or capital leases.

### Operating Lease

An **operating lease** is a short-term lease written usually for a period of time that is substantially shorter than the asset's useful life. The lessor assumes most of the risks of ownership, including maintenance, service, insurance, liability, and property taxes. The lessee can cancel an operating lease on short notice. Thus, the operating lease does not involve the long-term fixed future commitment of financial resources and is similar to renting. There are no balance sheet effects recorded with an operating lease, and the rental payments are treated as period expenses.

## Financial Lease

A **financial lease**, or capital lease, is a contract by which the lessee agrees to pay the lessor a series of payments whose sum equals or exceeds the purchase price of the asset. Typically, the total cash flows from the lease payments, the tax savings, and the residual value of the asset at the end of the lease will be sufficient to pay back the lessor's investment and provide a profit. Most financial leases are "net" leases, in that the fundamental ownership responsibilities such as maintenance, insurance, and property and sales taxes are placed upon the lessee. The lease agreement is a long-term agreement between both parties and is not cancelable. In the case of an unforeseen event, the contract may be cancelable, but the lessor will typically impose a substantial prepayment penalty. The decision to use financial leasing as a means of acquiring an asset is often viewed as an alternative to a purchase transaction using long-term debt financing to generate the necessary cash.

## Sale and Leaseback

A sale and leaseback is a fairly common arrangement where a firm sells an asset to a lender/lessor and then immediately leases back the property. The advantage to the seller/lessee is that the selling firm receives a large infusion of cash that may be used to finance other business activities. In return for this cash, the selling firm issues a long-term lease obligation to the lessor in order to make economic use of the asset during the lease period. Title to the asset is transferred to the lessor, and the lessor will realize any residual value the asset may have at the end of the lease. The lessee may realize a tax advantage in this situation if the lease involves a building on owned land. Land is not depreciable if owned outright, but the full amount of the lease payment may be tax-deductible. This allows the lessee to indirectly depreciate the cost of the land through the deductibility of the lease payment.

## Accounting Treatment of Leases

Accounting for leases has changed dramatically over time. Prior to 1977, lease financing was attractive to some firms because the lease obligation did not appear on the company's balance sheet. As a result, leasing was regarded as a form of "off-balance sheet financing." In 1977 the Financial Accounting Standards Board issued an accounting standard that clearly set out criteria distinguishing a capital lease from an operating lease. Any lease that does not meet the criteria for a capital lease must be classified as an operating lease. A lease is considered to be a capital lease if it meets any one of the following conditions:

1. The title of the asset being leased is transferred to the lessee at the end of the lease term.
2. The lease contains an option for the lessee to purchase the asset at a very low price.
3. The term of the lease is greater than or equal to 75% of the economic life of the asset.
4. The present value of the lease payments is greater than or equal to 90% of the fair value of the leased property.

A capital lease is recorded on the lessee's balance sheet as a lease asset with an associated lease liability. The amount of the asset and liability is equal to the present value of the minimum future lease payments. Thus, for capital leases, leasing no longer provides a source of off-balance sheet financing. Operating leases must be fully disclosed in the footnotes to the financial statements.

## Tax Treatment of Leases

For tax purposes, the lessee can deduct the full amount of the lease payment in a properly structured lease. The Internal Revenue Service (IRS) wants to be sure that the lease contract truly represents a lease and not an installment purchase of the asset. To assure itself that a true lease is present, the IRS will look for a meaningful residual value at the end of the lease term. This is usually construed to mean that the term of the lease cannot exceed 90% of the economic life of the asset. In addition, the lessee should not be given the option to purchase the asset for anything less than the fair market value of the leased asset at the end of the lease term. The lease payments should be reasonable in that they provide the lessor not only a return of principal, but a reasonable interest return as well. In addition, the lease term must be less than 30 years; otherwise it will be construed as an installment purchase of the asset. The IRS wants to assure itself that the transaction is not a disguised installment purchase that has more rapid payments which will lead to greater deductions than would be allowed from the depreciation deduction under an outright purchase. With leasing, the cost of any land is amortized in the lease payments. In an outright purchase of land, depreciation is not allowable. When the value of a lease includes land, lease financing can offer a tax advantage to the firm. Offsetting this tax advantage is the likely residual value of the land at the end of the lease period.

## Evaluating Lease Financing

To evaluate whether or not a lease financing proposal makes economic sense, it should be compared with financing the asset with debt. Whether leasing or borrowing is best will depend on the patterns of cash flow for each financing method and on the opportunity cost of funds. The method of analysis will require the calculation of the present values for the lease alternative and the present value of the borrowing alternative. The alternative with the lower present value of the cash outflows will be the better choice. The calculations can be rather extensive and complicated. Also, it should be recognized that the calculations do deal with uncertainty, which must be considered in making the final decision.

## Defining Terms

**Bond:** A long-term debt instrument issued by a corporation or government.

**Common stock:** The stock representing the most basic rights to ownership in the corporation.

**Financial lease:** A long-term lease that is not cancelable.

**Lease:** A contract under which one party, the owner of an asset (lessor), agrees to grant the use of the asset to another party (lessee), in exchange for periodic payments.

**Operating lease:** A short-term lease that is often cancelable.

**Preferred stock:** A type of stock that usually promises a fixed dividend, with the approval of the board of directors. It has preference over common stock in the payment of dividends and claims on assets.

**Term loan:** Debt originally scheduled for repayment in more than one year but generally less than ten years.

## **Rosalie T. Ruegg**

*National Institute of Standards and Technology*

**Risk assessment** provides decision makers with information about the **risk exposure** inherent in a given decision, that is, the probability that the outcome will be different from the "best-guess" estimate. Risk assessment also is concerned with the **risk attitude** of the decision maker—that is, the willingness of the decision maker to take a chance on an investment of uncertain outcome. Risk assessment techniques are typically used in conjunction with conventional methods of investment analysis, such as **net present value** (NPV), benefit-to-cost ratio (BCR), and rate-of-return (ROR) analysis; the risk assessment techniques are generally not used as "stand-alone" evaluation techniques. Techniques range from simple and partial to complex and comprehensive. Although none of these techniques take the risk out of making decisions, if used correctly, they can help the decision maker to make more informed choices in the face of uncertainty.

This chapter provides an overview of the following risk assessment techniques:

- Expected value analysis
- Mean-variance criterion and coefficient of variation
- Risk-adjusted discount rate technique
- Certainty equivalent technique

- Simulation analysis
- Decision analysis

Other techniques are also used to assess risks—for example, the mathematical/analytical technique and various combinations of techniques—but those covered here are the most widely used.

## 186.1 Expected Value (EV) Analysis

Expected value analysis provides a simple way of taking into account **uncertainty** in input values, but it does not provide an explicit measure of risk in the outcome. It is helpful in explaining and illustrating risk attitudes.

### How to Calculate EV

An expected value is the sum of the products of the dollar value of alternative outcomes and their probabilities of occurrence. That is, where  $a_{1-n}$  indicates values associated with alternative outcomes of a decision and  $p_{1-n}$  indicates the probabilities of occurrence of the alternative outcomes, the expected value (EV) of the decision is calculated as follows:

$$EV = a_1p_1 + a_2p_2 + \cdots a_np_n \quad (186.1)$$

**Example 186.1 - EV Analysis.** The following simplified example illustrates the combining of expected value analysis and net present value analysis to support a purchase decision.

Assume that the postal service must decide whether to buy a given piece of labor-saving equipment. Assume the unit purchase price of the equipment is \$100 000, the yearly operating cost is \$5000 (obtained by a fixed-price contract), and both costs are known with certainty. The annual labor cost savings, on the other hand, are uncertain but can be estimated in probabilistic terms, as shown in [Table 186.1](#) in the columns headed  $a_1$ ,  $p_1$ ,  $a_2$ , and  $p_2$ . The expected value calculations and the net present value calculations are also given in [Table 186.1](#).

**Table 186.1** Expected Value and Net Present Value Calculations

Year	Equipment Purchase (\$1000)	Operating Cost (\$1000)	$a_t$ (\$1000)	Labor Savings			PV Factor*	PV (\$1000)
				$p_1$	$a_2$ (\$1000)	$p_2$		
0	−100	—	—	—	—	—	1.00	−100
1		−5	25	0.8	50	0.2	0.93	23
2		−5	30	0.8	60	0.2	0.86	27
3		−5	30	0.7	60	0.3	0.79	27
4		−5	30	0.6	60	0.4	0.74	27
5		−5	30	0.8	60	0.2	0.68	21
Expected Net Present Value								25

**Present value** (PV) calculations are based on a discount rate of 8%. Probabilities sum to 1.0 in a given year.

If the equipment decision were based only on net present value calculated with the best-guess labor savings (column  $a_1$ ), the equipment purchase would be found to be uneconomic. But if the possibility of greater labor savings is taken into account by using the expected value of labor savings rather than the best guess, the conclusion is that over repeated applications the equipment should be cost-effective. The expected net present value of the labor-saving equipment is \$25 000 per unit.

## Advantages and Disadvantages of the EV Technique

An advantage of the technique is that it provides a predicted value that tends to be closer to the actual value than a simple best-guess estimate over repeated instances of the same event—provided, of course, that the input probabilities can be predicted with some accuracy.

A disadvantage of the EV technique is that it expresses the outcome as a single-value measure, such that there is no explicit measure of risk. Another is that the estimated outcome is predicated on many replications of the event—with the expected value in effect a weighted average of the outcome over many like events. But in the case of a single instance of an event, the expected value is unlikely to occur. This is analogous to the case of a single coin toss: The outcome will be either heads or tails, not the probabilistic-based weighted average of both.

## Expected Value and Risk Attitude

Expected values are useful in explaining risk attitude. Risk attitude may be thought of as a decision maker's preference of taking a chance on an uncertain money payout of known probability versus accepting a sure money amount. Suppose, for example, a person were given a choice between accepting the outcome of a fair coin toss, where heads means winning \$10 000 and tails means losing \$5000, and accepting a certain cash amount of \$2000. Expected value analysis can be used to evaluate and compare the choices. In this case the expected value is \$2500, which is \$500 more than the certain money amount. The "risk-neutral" decision maker will prefer the coin toss because of its higher expected value. The decision maker who prefers the \$2000 certain amount is demonstrating a "risk-averse" attitude. On the other hand, if the certain amount were raised to \$3000 and the first decision maker still preferred the coin toss, he or she would be demonstrating a "risk-taking" attitude. Such trade-offs can be used to derive a *utility function* that represents a decision maker's risk attitude.

The risk attitude of a given decision maker typically is a function of the amount at risk. Many people who are risk-averse when faced with the possibility of significant loss become risk-neutral, or even risk taking, when potential losses are small. Since decision makers vary substantially in their risk attitudes, there is a need to assess not only risk exposure—that is, the degree of risk inherent in the decision—but also the risk attitude of the decision maker.

## 186.2 Mean-Variance Criterion (MVC) and Coefficient of Variation (CV)

The MVC and CV can be useful in choosing among risky alternatives when the mean outcomes and standard deviations (variation from the mean) can be calculated.

### How to Use the MVC

Consider a choice between two projects—one with higher mean net benefits and a lower standard deviation than the other. This situation is illustrated in Fig. 186.1. In this case the project whose probability distribution is labeled B can be said to have stochastic dominance over the project labeled A. Project B is preferable to project A both on grounds that its output is likely to be higher and on grounds that it entails less risk of loss. But what if the alternative with the higher mean output entails higher risk of an unfavorable outcome, as illustrated in Fig. 186.2? If this were the case, the MVC would provide inconclusive results.

**Figure 186.1** Stochastic dominance as demonstrated by mean-variance criterion.

**Figure 186.2** Inconclusive results from mean-variance criterion.

## How to Calculate the CV

It is helpful to compute the coefficient of variation (CV) to determine the relative risk of two alternative projects. The CV indicates which alternative has the lower risk per unit of project output. Risk-averse decision makers will prefer the alternative with the lower CV, other things being equal. The CV is calculated as follows:

$$CV = \sigma/\mu \quad (186.2)$$

where

CV = coefficient of variation

$\sigma$  = standard deviation

$\mu$  = mean

## Advantages and Disadvantages of the MVC and CV Techniques

The principal advantage of these techniques is that they provide quick, easy-to-calculate indications of the returns and risk exposure of one project relative to another. The principal disadvantage is that the MVC does not provide a clear indication of preference when the alternative with the higher mean output has the higher risk, or vice versa.

## 186.3 Risk-Adjusted Discount Rate (RADR) Technique

---

The RADR technique takes account of risk through the **discount rate**. If a project's benefit stream is riskier than that of the average project in the decision maker's portfolio, a higher than normal discount rate is used; if the benefit stream is less risky, a lower than normal discount rate is used. If costs are the source of the higher-than-average uncertainty, a lower than normal discount rate is used, and vice versa. The greater the variability in benefits or costs, the greater the adjustment in the discount rate.

## How to Calculate the RADR

The RADR is calculated as follows:

$$RADR = RFR + NRA + XRA \quad (186.3)$$

where

RADR = risk-adjusted discount rate

RFR = risk-free discount rate, generally set equal to the U.S. Treasury bill rate

NRA = "normal" risk adjustment to account for the average level of risk encountered in the decision maker's operations

XRA = extra risk adjustment to account for risk greater or less than normal risk

**Example 186.2<sup>3</sup> RADR Technique.** A company is considering an investment with high payoff potential and high risk. The normal discount rate used by the company, computed as the weighted average cost of capital, is 12%. The treasury bill rate, taken as the risk-free rate, is 8%. The normal risk adjustment factor is 5%. This investment is twice as risky as the company's average investment, such that the risk adjustment factor is 10%. Hence, the RADR is 18%. The projected cost and revenue streams and the discounted present values are shown in [Table 186.2](#).

**Table 186.2** RADR Example

Year	Costs (\$M)	Revenue (\$M)	PV Costs (\$M)	PV Revenue (\$M)	NPV (\$M)
0	80		80	—	−80
1	5	20	4	17	13
2	5	20	4	14	10
3	5	20	4	12	8
4	5	20	3	10	7
5	5	20	3	9	6
6	5	20	3	7	4
7	5	20	2	6	4
Total NPV					−28

Note: Costs are discounted with a discount rate of 12%, revenue with a discount rate of 18%.

## Advantages and Disadvantages of the RADR Technique

One advantage of RADR is that it provides a way to account for both risk exposure and risk attitude. Furthermore, RADR does not require any additional calculation steps once the value(s) of the RADR is established. One disadvantage is that it provides only an approximate adjustment. The value of the RADR is typically a rough estimate based on sorting investments into risk categories and adding a "fudge factor" to account for the decision maker's risk attitude. RADR is not a fine-tuned measure of the inherent risk associated with variations in cash flows. Further, it typically is biased toward investments with short payoffs, because it applies a constant RADR over the entire time period even though risk may vary over time.

## 186.4 Certainty Equivalent (CE) Technique

The CE technique adjusts investment cash flows by a factor that will convert the measure of

economic worth to a "certainty equivalent" amount—the amount a decision maker will find equally acceptable to a given investment with an uncertain outcome. Central to the technique is the derivation of the certainty equivalent factor (CEF), which is used to adjust net cash flows for uncertainty.

## Establishing CEFs and Applying the CEF Technique

Risk exposure can be built into the CEF by establishing categories of risky investments for the decision maker's organization and linking the CEF to the coefficient of variation of the returns—greater variation translating into smaller CEF values. The procedure is as follows:

1. Divide the organization's portfolio of projects into risk categories. Examples of investment risk categories for a given company might be the following: low-risk investments—expansion of current product lines and equipment replacement; moderate-risk investments—development of "spin-off" product lines and introduction of new equipment; and high-risk investments—new product development and new business acquisition.
2. Estimate the coefficients of variation (see section 186.2) for each investment-risk category—for example, on the basis of historical risk-return data.
3. Assign CEFs by year according to the coefficients of variation, with the highest risk projects being given the lowest CEFs. If the objective is to reflect only risk exposure, set the CEFs such that a risk-neutral decision maker will be indifferent between receiving the estimated certain amount and receiving the uncertain investment. If the objective is to reflect risk attitude as well as risk exposure, set the CEFs such that the risk-averse or risk-taking decision maker will be indifferent.
4. Select the conventional measure of economic worth to be used—such as the measure of net present value (i.e., net benefits).
5. Estimate the net cash flows and decide in which investment-risk category the project in question fits.
6. Multiply the yearly net cash flow amounts by the appropriate CEFs.
7. Discount the adjusted yearly net cash flow amounts with a risk-free discount rate (a risk-free discount rate is used because the risk adjustment is accomplished by the CEFs).
8. Proceed with the remainder of the analysis in the conventional way.

In summary, the certainty equivalent net present value is calculated as follows:

$$NPV_{CE} = \sum_{t=0}^N [(CEF_t(B_t - C_t)) / (1 + RFD)^t] \quad (186.4)$$

where

$NPV_{CE}$  = net present value adjusted for uncertainty by the CE technique

$B_t$  = estimated benefits in time period  $t$

$C_t$  = estimated costs in time period  $t$

RFD = risk-free discount rate

**Example 186.3 - CE Technique.** Table 186.3 illustrates the use of this technique for adjusting net present value calculations for a high-risk investment in a new plant startup. The CEF is set at 0.76 and is assumed to be constant with respect to time.

**Table 186.3** Applying the CE Technique—Investment-Risk Category: High Risk—New Plant Startup

Yearly Net Cash Flow (\$M)		CV	CEF	RFD Discount Factors*	NPV (\$M)
1	−100	0.22	0.76	0.94	−71
2	−100	0.22	0.76	0.89	−68
3	20	0.22	0.76	0.84	13
4	30	0.22	0.76	0.79	18
5	45	0.22	0.76	0.75	26
6	65	0.22	0.76	0.70	35
7	65	0.22	0.76	0.67	33
8	65	0.22	0.76	0.63	31
9	50	0.22	0.76	0.59	22
10	50	0.22	0.76	0.56	21
Total NPV					60

\*The RFD is assumed equal to 6%.

## Advantages and Disadvantages of the CE Technique

A principal advantage of the CE technique is that it can be used to account for both risk exposure and risk attitude. Another is that it separates the adjustment of risk from discounting and makes it possible to make more precise risk adjustments over time. A major disadvantage is that the estimation of CEF is only approximate.

## 186.5 Simulation Technique

Simulation entails the iterative calculation of the measure of economic worth from probability functions of the input variables. The results are expressed as a probability density function and as a cumulative distribution function. The technique thereby enables explicit measures of risk exposure to be calculated. A conventional method is used to calculate economic worth; a computer is employed to sample repeatedly—hundreds of times—and make the calculations.

## How to Perform Simulation

1. Express variable inputs as probability functions. Where there are interdependencies among input values, multiple probability density functions, tied to one another, may be needed.
2. For each input with a probability function, draw randomly an input value; for each input with only a single value, take that value for calculations.
3. Use the input values to calculate the economic measure of worth and record the results.
4. If inputs are interdependent, such that input  $X$  is a function of input  $Y$ , first draw the value of  $Y$ , then draw randomly from the  $X$  values that correspond to the value of  $Y$ .
5. Repeat the process many times until the number of results is sufficient to construct a probability density function and a cumulative distribution function.
6. Construct the probability density function and the cumulative distribution function for the economic **measure of project worth** and perform statistical analysis of the variability.

## Advantages and Disadvantages of Simulation

The strong advantage of simulation is that it expresses the results in probabilistic terms, thereby providing detailed assessment of risk exposure. A disadvantage is that it does not explicitly treat risk attitude; however, by providing a clear measure of risk exposure, it facilitates the implicit incorporation of risk attitude in the decision. The necessity of expressing inputs in probabilistic terms and the extensive calculations are also often considered disadvantages.

## 186.6 Decision Analysis

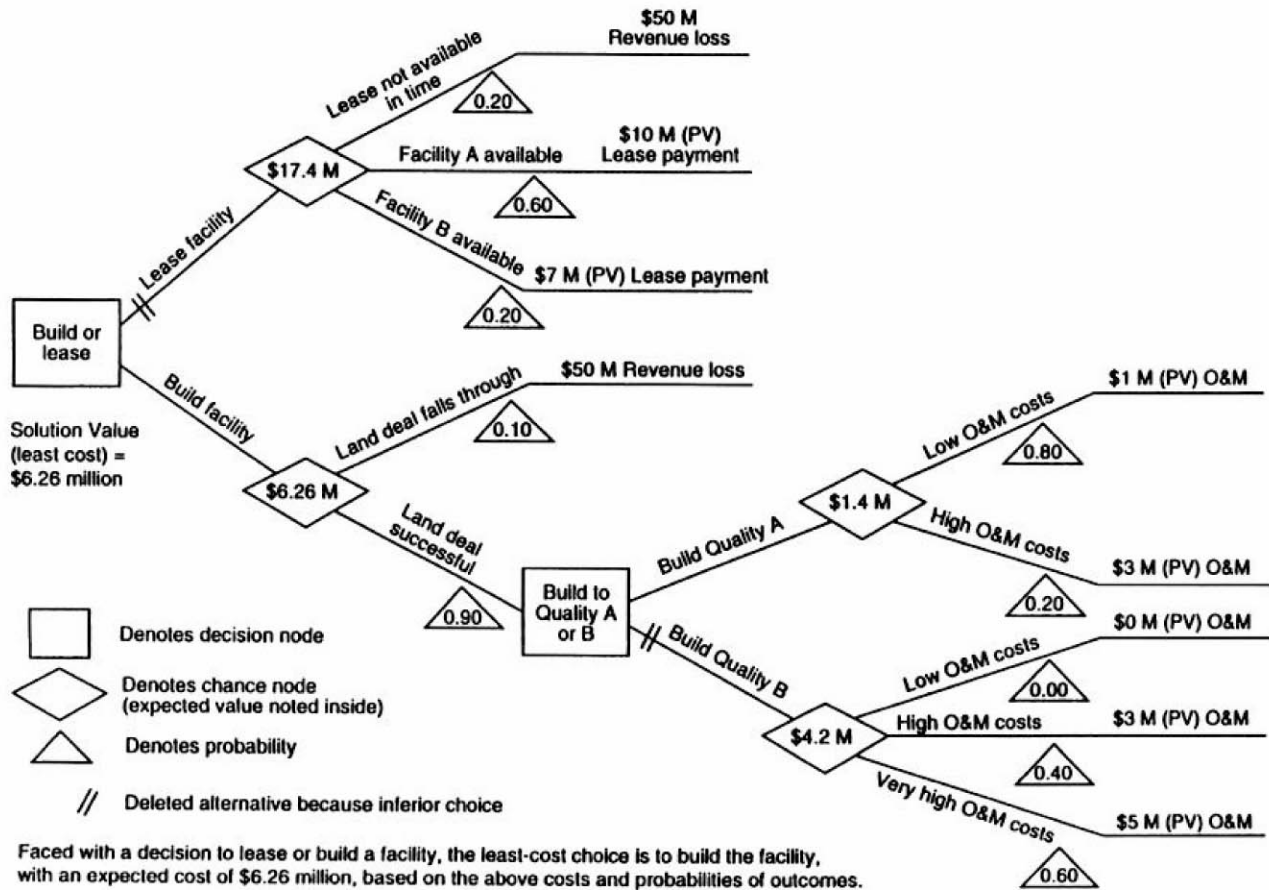

---

Decision analysis is a versatile technique that enables both risk exposure and risk attitude to be taken into account in the economic assessment. It diagrams possible choices, costs, benefits, and probabilities for a given decision problem in *decision trees*, which are useful in understanding the possible choices and outcomes.

## How to Perform Decision Analysis

Although it is not possible to capture the richness of this technique in a brief overview, a simple decision tree (shown in [Fig. 186.3](#)) is presented to give a sense of how the technique is used. The decision problem is whether to lease or build a facility. The decision must be made now, based on uncertain data. The decision tree helps to structure and analyze the problem. The tree is constructed left to right and analyzed right to left. The tree starts with a box representing a decision juncture or node—in this case, whether to lease or build a facility. The line segments branching from the box represent the two alternative paths, the upper one the lease decision and the lower one the build decision.

**Figure 186.3** Decision tree illustration.

## Advantages and Disadvantages of Decision Analysis

An advantage of this technique is that it helps decision makers to understand the problem and to compare alternative solutions. Another advantage is that, in addition to treating risk exposure, it can also accommodate risk attitude by converting benefits and costs to utility values (not addressed in this chapter). A disadvantage is that the technique as typically applied does not provide an explicit measure of the variability of the outcome.

## Defining Terms

**Discount rate:** The minimum acceptable rate of return used in converting benefits and costs occurring at different times to their equivalent values at a common time.

**Measures of project worth:** Economic methods that combine project benefits (savings) and costs in various ways to evaluate the economic value of a project. Examples are life-cycle costs, net benefits or net savings, benefit-to-cost ratio or savings-to-investment ratio, and adjusted internal rate of return.

**Net present value:** Present value benefits minus present value costs.

**Present value:** Time-equivalent value at the present of past, present, and future cash flows.

**Risk assessment:** As applied to economic decisions, the body of theory and practice that helps decision makers assess their risk exposures and risk attitudes in order to increase the probability that they will make economic choices that are best for them.

**Risk attitude:** The willingness of decision makers to take chances on investments of uncertain, but predictable, outcome. Risk attitudes may be classified as risk-averse, risk-neutral, and risk taking.

**Risk exposure:** The probability of investing in a project whose economic outcome is less favorable than what is economically acceptable.

**Uncertainty:** As used in the context of this chapter, a state of not being certain about the values of variable inputs to an economic analysis.

### 187.2 Advantages and Disadvantages

#### Harold E. Marshall

*National Institute of Standards and Technology*

**Sensitivity analysis** measures the impact on project outcomes of changing one or more key input values about which there is uncertainty. For example, a pessimistic, expected, and optimistic value might be chosen for an uncertain variable. Then an analysis could be performed to see how the outcome changes as each of the three chosen values is considered in turn, with other things held the same.

In engineering economics, sensitivity analysis measures the economic impact resulting from alternative values of uncertain variables that affect the economics of the project. When computing **measures of project worth**, for example, sensitivity analysis shows just how sensitive the economic payoff is to uncertain values of a critical input, such as the **discount rate** or project maintenance costs expected to be incurred over the project's **study period**. Sensitivity analysis reveals how profitable or unprofitable the project might be if input values to the analysis turn out to be different from what is assumed in a single-answer approach to measuring project worth.

Sensitivity analysis can also be performed on different combinations of input values. That is, several variables are altered at once and then a measure of worth is computed. For example, one scenario might include a combination of all pessimistic values, another all expected values, and a third all optimistic values. Note, however, that sensitivity analysis can in fact be misleading [Hillier, 1969] if all pessimistic assumptions or all optimistic assumptions are combined in calculating economic measures. Such combinations of inputs would be unlikely in the real world.

Sensitivity analysis can be performed for any measure of worth. And since it is easy to use and understand, it is widely used in the economic evaluation of government and private-sector projects. Office of Management and Budget [1992] Circular A-94 recommends sensitivity analysis to federal agencies as one technique for treating uncertainty in input variables. And the American Society for Testing and Materials (ASTM) [1994], in its *Standard Guide for Selecting Techniques for Treating Uncertainty and Risk in the Economic Evaluation of Buildings and Buildings Systems*, describes sensitivity analysis for use in government and private-sector applications.

## 187.1 Sensitivity Analysis Applications

How to use sensitivity analysis in engineering economics is best illustrated with examples of applications. Three applications are discussed. The first two focus on changes in project worth as a function of the change in one variable only. The third allows for changes in more than one uncertain variable.

The results of sensitivity analysis can be presented in text, tables, or graphs. The following illustration of sensitivity analysis applied to a programmable control system uses text and a simple table. Subsequent illustrations use graphs. The advantage of using a graph comes from being able to show in one picture the outcome possibilities over a range of input variations for one or several input factors.

### Sensitivity Table for Programmable Control System

Consider a decision on whether or not to install a programmable time clock to control heating, ventilating, and air conditioning (HVAC) equipment in a commercial building. The time clock would reduce electricity consumption by turning off that part of the HVAC equipment that is not needed during hours when the building is unoccupied.

Using **net savings** (NS) as the measure of project worth, the time clock is acceptable on economic grounds if its NS is positive—that is, if its **present value** savings exceed present value costs. The control system purchase and maintenance costs are felt to be relatively certain. The savings from energy reductions resulting from the time clock, however, are not certain. They are a function of three factors: the initial price of energy, the rate of change in energy prices over the life cycle of the time clock, and the number of kilowatt hours (kWh) saved. Two of these, the initial price of energy and the number of kWh saved, are relatively certain. But future energy prices are not.

To test the sensitivity of NS to possible energy price changes, three values of energy price change are considered: a low rate of energy price escalation (slowly increasing benefits from energy savings), a moderate rate of escalation (moderately increasing benefits), and a high rate of escalation (rapidly increasing benefits).

Table 187.1 shows three NS estimates that result from repeating the NS computation for each of the three energy price escalation rates.

**Table 187.1** Energy Price Escalation Rates

Energy Price Escalation Rate	Net Savings
Low	\$-15 000
Moderate	20 000
High	50 000

To appreciate the significance of these findings, it is helpful to consider what extra information is gained over the conventional single-answer approach, where, say, a single NS estimate of \$20 000 was computed. Table 187.1 shows that the project could return up to \$50 000 in NS if future

energy prices escalated at a high rate. On the other hand, it is evident that the project could lose as much as \$15 000. This is considerably less than **breakeven**, where the project would at least pay for itself. It is also \$35 000 less than what was calculated with the single-answer approach. Thus, sensitivity analysis reveals that accepting the time clock could lead to an uneconomic outcome.

There is no explicit measure of the likelihood that any one of the NS outcomes will happen. The analysis simply shows what the outcomes will be under alternative conditions. However, if there is reason to expect energy prices to rise, at least at a moderate rate, then the project very likely will make money, other factors remaining the same. This adds helpful information over the traditional single-answer approach to measures of project worth.

## Sensitivity Graph for Gas Heating Systems

Figure 187.1 shows how sensitive NS is to the time over which two competing gas heating systems might be used in a building. The sensitivity graph helps you decide which system to choose on economic grounds.

**Figure 187.1** Sensitivity of net savings to holding period.

Assume that you have an old electric heating system that you are considering replacing with a gas furnace. You have a choice between a high-efficiency or low-efficiency gas furnace. You expect either to last at least 15 to 20 years. And you do not expect any significant difference in building resale value or salvage value from selecting one system over the other. So you compute the NS of each gas furnace as compared to the old electric system. You will not be able to say which system is more economical until you decide how long you will hold the building before selling it. This is where the sensitivity graph is particularly helpful.

Net savings are measured on the vertical axis, and time on the horizontal axis. The longer you hold the building, the greater will be the present value of NS from installing either of the new systems, up to the estimated life of the systems. But note what happens in the ninth year. One line crosses over another. This means that the low-efficiency system is more **cost-effective** than the high-efficiency system for any holding period up to 9 years. To the left of the crossover point, NS

values are higher for the low-efficiency system than for the high-efficiency system. But for longer holding periods, the high-efficiency system is more cost-effective than the low-efficiency system. This is shown to the right of the crossover point.

How does the sensitivity graph help you decide which system to install? First, it shows that neither system is more cost-effective than the other for all holding periods. Second, it shows that the economic choice between systems is sensitive to the uncertainty of how long you hold the building. You would be economically indifferent between the two systems only if you plan to hold the building 9 years. If you plan to hold the building longer than 9 years, for example, then install the high-efficiency unit. But if you plan to hold it less than 9 years, then the low-efficiency unit is the better economic choice.

## Spider Diagram for a Commercial Building Investment

Another useful graph for sensitivity analysis is the **spider diagram**. It presents a snapshot of the potential impact of uncertain input variables on project outcomes. [Figure 187.2](#) shows—for a prospective commercial building investment—the sensitivity of the **adjusted internal rate of return (AIRR)** to three uncertain variables: project life (PL); the reinvestment rate (RR); and operation, maintenance, and replacement costs (OM&R). The spider diagram helps the investor decide if the building is likely to be a profitable investment.

**Figure 187.2** Spider diagram showing sensitivity of the adjusted internal rate of return to variations in uncertain variables. PL = project life; RR = reinvestment rate; and OM&R = operation, maintenance, and replacement costs.

Each of the three uncertain variables is represented by a labeled function that shows what AIRR

value results from various values of the uncertain variable. (Although these functions are not necessarily linear, they are depicted as linear here to simplify exposition.) For example, the downward-sloping OM&R function indicates that the AIRR is inversely proportional to OM&R costs. By design, the OM&R function (as well as the other two functions) passes through the horizontal axis at the "best-guess" estimate of the AIRR (15% in this case), based on the best-guess estimates of the three uncertain variables. Other variables (e.g., occupancy rate) will impact the AIRR, but these are assumed to be known for the purpose of this analysis. Since each of the variables is measured by different units (years, percent, and money), the vertical axis is denominated in positive and negative percent changes from the best-guess values fixed at the horizontal axis. The AIRR value corresponding to any given percent variation indicated by a point on the function is found by extending a line perpendicular to the horizontal axis and directly reading the AIRR value. Thus a 30% increase in the best-guess reinvestment rate would yield a 25% AIRR, assuming that other values remain unchanged. Note that if the measure of AIRR were also given in percent differences, then the best-guess AIRR would be at the origin.

The spider diagram's contribution to decision making is its instant picture of the relative importance of several uncertain variables. In this case, the lesser the slope of a function is, the more sensitive is the AIRR to that variable. For example, any given percent change in OM&R will have a greater impact on the AIRR than will an equal percent change in RR or PL, and a percentage change in RR will have a greater impact than an equal percentage change in PL. Thus an investor will want to know as much as possible about likely OM&R costs for this project, because a relatively small variation in estimated costs could make the project a loser.

## 187.2 Advantages and Disadvantages

---

There are several advantages of using sensitivity analysis in engineering economics. First, it shows how significant any given input variable is in determining a project's economic worth. It does this by displaying the range of possible project outcomes for a range of input values, which shows decision makers the input values that would make the project a loser or a winner. Sensitivity analysis also helps identify critical inputs in order to facilitate choosing where to spend extra resources in data collection and in improving data estimates.

Second, sensitivity analysis is an excellent technique to help in anticipating and preparing for the "what if" questions that are asked in presenting and defending a project. For instance, when one is asked what the outcome will be if operating costs are 50% more expensive than expected, one will be ready with an answer. Generating answers to "what if" questions will help assess how well a proposal will stand up to scrutiny.

Third, sensitivity analysis does not require the use of probabilities, as do many techniques for treating uncertainty.

Fourth, sensitivity analysis can be used on any measure of project worth.

And, finally, sensitivity analysis can be used when there is little information, resources, and time for more sophisticated techniques.

The major disadvantage of sensitivity analysis is that there is no explicit probabilistic measure of **risk exposure**. That is, although one might be sure that one of several outcomes might happen, the analysis contains no explicit measure of their respective likelihoods.

## Defining Terms

**Adjusted internal rate of return (AIRR):** The annual percentage yield from a project over the study period, taking into account the returns from reinvested receipts.

**Breakeven:** A combination of benefits (savings or revenues) that just offset costs, such that a project generates neither profits nor losses.

**Cost-effective:** The condition whereby the present value benefits (savings) of an investment alternative exceed its present value costs.

**Discount rate:** The minimum acceptable rate of return used in converting benefits and costs occurring at different times to their equivalent values at a common time. Discount rates reflect the investor's time value of money (or opportunity cost). "Real" discount rates reflect time value apart from changes in the purchasing power of the dollar (i.e., exclude inflation or deflation) and are used to discount constant dollar cash flows. "Nominal" or "market" discount rates include changes in the purchasing power of the dollar (i.e., include inflation or deflation) and are used to discount current dollar cash flows.

**Measures of project worth:** Economic methods that combine project benefits (savings) and costs in various ways to evaluate the economic value of a project. Examples are life-cycle costs, net benefits or net savings, benefit-to-cost ratio or savings-to-investment ratio, and adjusted internal rate of return.

**Net savings:** The difference between savings and costs, where both are discounted to present or annual values. The net savings method is used to measure project worth.

**Present value:** The time-equivalent value at a specified base time (the present) of past, present, and future cash flows.

**Risk exposure:** The probability that a project's economic outcome is different from what is desired (the target) or what is acceptable.

**Sensitivity analysis:** A technique for measuring the impact on project outcomes of changing one or more key input values about which there is uncertainty.

**Spider diagram:** A graph that compares the potential impact, taking one input at a time, of several uncertain input variables on project outcomes.

**Study period:** The length of time over which an investment is evaluated.

A major portion of the projected **life-cycle cost (LCC)** for a given product, system, or structure is traceable to decisions made during conceptual and preliminary design. These decisions pertain to operational requirements, performance and effectiveness factors, the design configuration, the maintenance concept, production quantity, utilization factors, logistic support, and disposal. Such decisions guide subsequent design and production activities, product distribution functions, and aspects of sustaining system support. Accordingly, if the final life-cycle cost is to be minimized, it is essential that a high degree of cost emphasis be applied during the early stages of system design and development.

### 188.1 The Life-Cycle Costing Situation

---

The combination of rising inflation, cost growth, reduction in purchasing power, budget limitations, increased competition, and so on has created an awareness and interest in the total cost of products, systems, and structures. Not only are the acquisition costs associated with new systems rising, but the costs of operating and maintaining systems already in use are also

increasing rapidly. This is due primarily to a combination of inflation and cost growth factors traceable to the following:

1. Poor quality of products, systems, and structures in use
2. Engineering changes during design and development
3. Changing suppliers in the procurement of system components
4. System production and/or construction changes
5. Changes in logistic support capability
6. Estimating and forecasting inaccuracies
7. Unforeseen events and problems

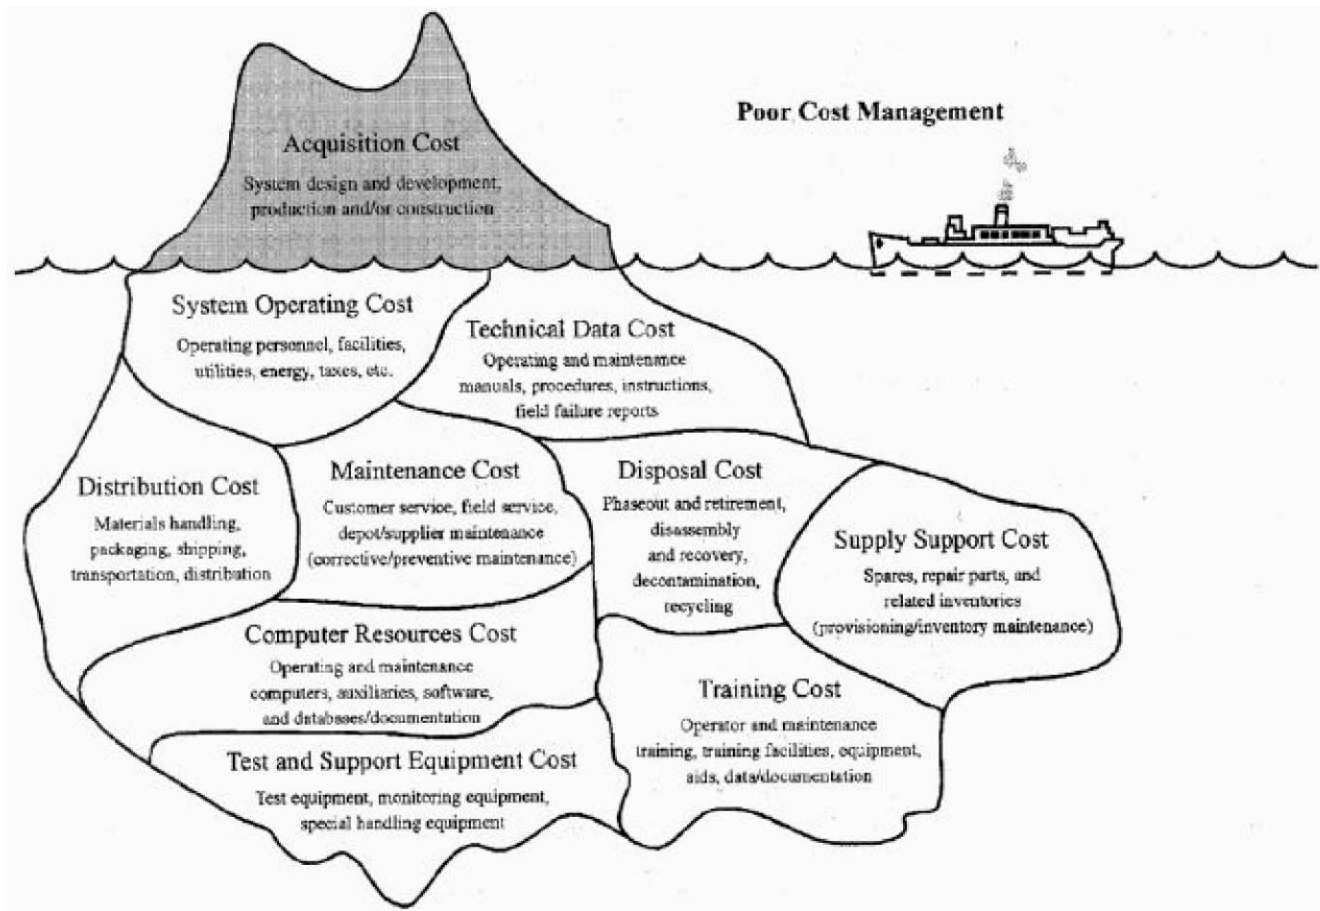

Experience indicates that cost growth due to various causes has ranged from 5 to 10 times the rate of inflation over the past several decades. At the same time, budget allocations for many programs are decreasing from year to year. The result is that fewer resources are available for acquiring and operating new systems or products and for maintaining and supporting existing systems. Available funds for projects, when inflation and cost growth are considered, are decreasing rapidly.

The current economic situation is further complicated by some additional problems related to the actual determination of system and/or product cost. Some of these are:

1. Total system cost is often not visible, particularly those costs associated with system operation and support. The cost visibility problem is due to an "iceberg" effect, as is illustrated in [Fig. 188.1](#).
2. Individual cost factors are often improperly applied. Costs are identified and often included in the wrong category; variable costs are treated as fixed (and vice versa); indirect costs are treated as direct costs; and so on.
3. Existing accounting procedures do not always permit a realistic and timely assessment of total cost. In addition, it is often difficult (if not impossible) to determine costs on a functional basis.
4. Budgeting practices are often inflexible regarding the shift in funds from one category to another, or from year to year, to facilitate cost improvements in system acquisition and utilization.

**Figure 188.1** The problem of total cost visibility.

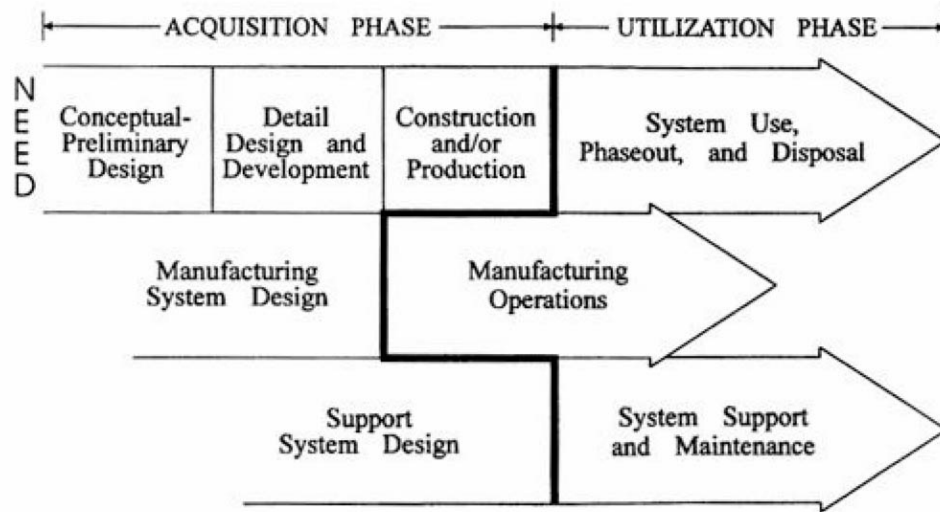

The current trends of inflation and cost growth, combined with these additional problems, have led to inefficiencies in the utilization of valuable resources. Systems and products have been developed that are not cost-effective. It is anticipated that these conditions will become worse unless an increased degree of cost consciousness is assumed by engineers. Economic feasibility studies must address all aspects of life-cycle cost, not just portions thereof.

Life-cycle cost is determined by identifying the applicable functions in each phase of the life cycle, costing these functions, applying the appropriate costs by function on a year-to-year basis, and then accumulating the costs over the entire span of the life cycle. Life-cycle cost must include all producer and consumer costs to be complete.

## 188.2 Cost Generated over the Life Cycle

Life-cycle cost includes all costs associated with the product, system, or structure as applied over the defined life cycle. The life cycle and the major functions associated with each phase are illustrated in [Fig. 188.2](#). Life-cycle costing is employed in the evaluation of alternative system design configurations, alternative production schemes, alternative logistic support policies, alternative disposal concepts, and so on. The life cycle, tailored to the specific system being addressed, forms the basis for life-cycle costing.

**Figure 188.2** Product, process, and support life cycles.

There are many technical and nontechnical decisions and actions required throughout the product or system life cycle. Most actions, particularly those in the earlier phases, have life-cycle implications and greatly affect life-cycle cost. The analysis constitutes a step-by-step approach employing life-cycle cost figures of merit as criteria to arrive at a cost-effective solution. This analysis process is iterative in nature and can be applied to any phase of the life cycle of the product, system, or structure. Cost emphasis throughout the system/product life cycle is summarized in the following sections.

## Conceptual System Design

In the early stages of system planning and conceptual design, when requirements are being defined, quantitative cost figures of merit should be established to which the system or product is to be designed, tested, produced (or constructed), and supported. A **design-to-cost (DTC)** goal may be adopted to establish cost as a system or product design constraint, along with performance, effectiveness, capacity, accuracy, size, weight, reliability, maintainability, supportability, and so on. Cost must be an active rather than a resultant factor throughout the system design process.

## Preliminary System Design

With quantitative cost requirements established, the next step includes an iterative process of synthesis, trade-off and optimization, and system/product definition. The criteria defined in the conceptual system design are initially allocated, or apportioned, to various segments of the system to establish guidelines for the design and/or the procurement of needed element(s). Allocation is accomplished from the system level down to the level necessary to provide an input to design and also to ensure adequate control. The factors projected reflect the target cost per individual unit (i.e., a single equipment unit or product in a deployed population) and are based on system operational requirements, the system maintenance concept, and the disposal concept.

As system development evolves, various approaches are considered that may lead to a preferred configuration. Life-cycle cost analyses are accomplished in (1) evaluating each possible candidate, with the objective of ensuring that the candidate selected is compatible with the established cost targets, and (2) determining which of the various candidates being considered is preferred from an overall cost-effectiveness standpoint. Numerous trade-off studies are accomplished, using life-cycle cost analysis as an evaluation tool, until a preferred design configuration is chosen. Areas of compliance are justified, and noncompliant approaches are discarded. This is an iterative process with an active-feedback and corrective-action loop.

## Detail Design and Development

As the system or product design is further refined and design data become available, the life-cycle cost analysis process involves the evaluation of specific design characteristics (as reflected by design documentation and engineering or prototype models), the prediction of cost-generating sources, the estimation of costs, and the projection of life-cycle cost as a **life-cycle cost profile (LCCP)**. The results are compared with the initial requirement and corrective action is taken as necessary. Again, this is an iterative process, but at a lower level than what is accomplished during preliminary system design.

## Production, Utilization, and Support

Cost concerns in the production, utilization, support, and disposal stages of the system or product life cycle are addressed through data collection, analysis, and an assessment function. High-cost contributors are identified, cause-and-effect relationships are defined, and valuable information is gained and utilized for the purposes of product improvement through redesign or reengineering.

## 188.3 The Cost Breakdown Structure

---

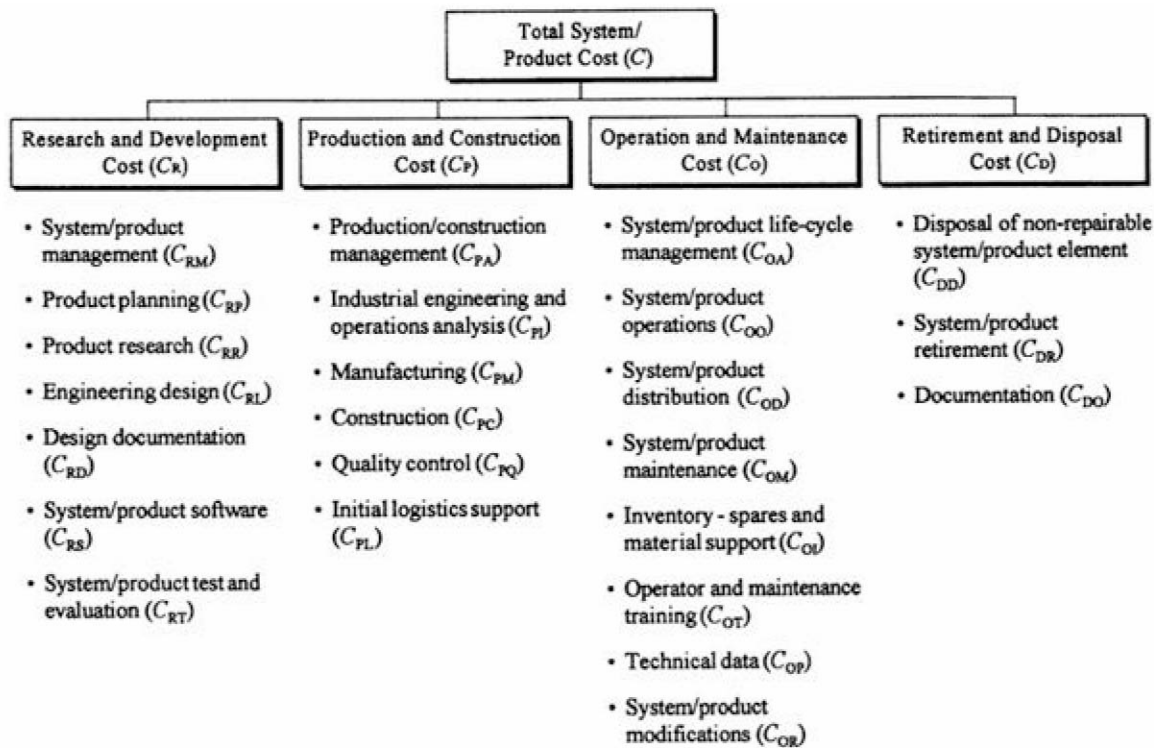

In general, costs over the life-cycle fall into categories based on organizational activity needed to bring a system into being. These categories and their constituent elements constitute a **cost breakdown structure (CBS)**, as illustrated in [Fig. 188.3](#). The main CBS categories are as follows:

1. *Research and development cost.* Initial planning, market analysis, feasibility studies, product research, requirements analysis, engineering design, design data and documentation, software, test and evaluation of engineering models, and associated management functions.
2. *Production and construction cost.* Industrial engineering and operations analysis, manufacturing (fabrication, assembly, and test), facility construction, process development, production operations, quality control, and initial logistic support requirements (e.g., initial consumer support, the manufacture of spare parts, the production of test and support equipment, etc.).
3. *Operation and support cost.* Consumer or user operations of the system or product in the field, product distribution (marketing and sales, transportation, and traffic management), and sustaining maintenance and logistic support throughout the system or product life cycle (e.g.,

customer service, maintenance activities, supply support, test and support equipment, transportation and handling, technical data, facilities, system modifications, etc.).

4. *Retirement and disposal cost.* Disposal of nonrepairable items throughout the life cycle, system/product retirement, material recycling, and applicable logistic support requirements.

**Figure 188.3** A general cost breakdown structure.

The cost breakdown structure links objectives and activities with organizational resource requirements. It constitutes a logical subdivision of cost by functional activity area, major system elements, and/or one or more discrete classes of common or like items. The CBS provides a means for initial resource allocation, cost monitoring, and cost control.

## 188.4 Life-Cycle Cost Analysis

The application of life-cycle costing methods during product and system design and development is realized through the accomplishment of **life-cycle cost analyses (LCCA)**. A life-cycle cost analysis may be defined as a systematic analytical process of evaluating various designs or alternative courses of action with the objective of choosing the best way to employ scarce resources.

Where feasible alternative solutions exist for a specific problem and a decision is required for the

selection of a preferred approach, there is a formal analysis process that should be followed. Specifically, the analyst should define the need for analysis, establish the analysis approach, select a model to facilitate the evaluation process, generate the appropriate information for each alternative being considered, evaluate each alternative, and recommend a proposed solution that is responsive to the problem.

## **Cost Analysis Goals**

There are many questions that the decision maker might wish to address. There may be a single overall analysis goal (e.g., design to minimum life-cycle cost) and any number of subgoals. The primary question should be as follows: What is the purpose of the analysis, and what is to be learned through the analysis effort?

In many cases the nature of the problem appears to be obvious, but its precise definition may be the most difficult part of the entire process. The design problem must be defined clearly and precisely and presented in such a manner as to be easily understood by all concerned. Otherwise, it is doubtful whether an analysis of any type will be meaningful. The analyst must be careful to ensure that realistic goals are established at the start of the analysis process and that these goals remain in sight as the process unfolds.

## **Analysis Guidelines and Constraints**

Subsequent to definition of the problem and the goals, the cost analyst must define the guidelines and constraints (or bounds) within which the analysis is to be accomplished. Guidelines are composed of information concerning such factors as the resources available for conducting the analysis (e.g., necessary labor skills, availability of appropriate software, etc.), the time schedule allowed for completion of the analysis, and/or related management policy or direction that may affect the analysis.

In some instances a decision maker or manager may not completely understand the problem or the analysis process and may direct that certain tasks be accomplished in a prescribed manner or time frame that may not be compatible with the analysis objectives. On other occasions a manager may have a preconceived idea as to a given decision outcome and direct that the analysis support the decision. Also, there could be external inhibiting factors that may affect the validity of the analysis effort. In such cases the cost analyst should make every effort to alleviate the problem by educating the manager. Should any unresolved problems exist, the cost analyst should document them and relate their effects to the analysis results.

Relative to the technical characteristics of a system or product, the analysis output may be constrained by bounds (or limits) that are established through the definition of system performance factors, operational requirements, the maintenance concept, and/or through advanced program planning. For example, there may be a maximum weight requirement for a given product, a minimum reliability requirement, a maximum allowable first cost per unit, a minimum rated capacity, and so on. These various bounds, or constraints, should provide for trade-offs in the evaluation of alternatives. Candidates that fall outside these bounds are not allowable.

## Identification of Alternatives

Within the established bounds and constraints, there may be any number of approaches leading to a possible solution. All possible alternatives should be considered, with the most likely candidates selected for further evaluation. Alternatives are frequently proposed for analysis even though there seems to be little likelihood that they will prove feasible. This is done with the thought that it is better to consider many alternatives than to overlook one that may be very good. Alternatives not considered cannot be adopted, no matter how desirable they may actually prove to be.

## Applying the Cost Breakdown Structure

Applying the cost breakdown structure is one of the most significant steps in life-cycle costing. The CBS constitutes the framework for defining life-cycle cost categories and provides the communications link for cost reporting, analysis, and ultimate cost control.

In developing the CBS one needs to proceed to the depth required to provide the necessary information for a true and valid assessment of the system or product life-cycle cost, identify high-cost contributors and enable determination of the cause-and-effect relationships, and illustrate the various cost parameters and their application in the analysis. Traceability is required from the system-level LCC figure of merit to the specific input factor.

## 188.5 Cost Treatment over the Life Cycle

---

With the system/product cost breakdown structure defined and cost-estimating approaches established, it is appropriate to apply the resultant data to the system life cycle. To accomplish this, the cost analyst needs to understand the steps required in developing cost profiles that include aspects of inflation, the effects of learning curves, the time value of money, and so on.

In developing a cost profile, there are different procedures that may be used. The following steps are suggested:

1. Identify all activities throughout the life cycle that will generate costs of one type or another. This includes functions associated with planning, research and development, test and evaluation, production/construction, product distribution, system/product operational use, maintenance and logistic support, and so on.
2. Relate each activity identified in step 1 to a specific cost category in the cost breakdown structure. All program activities should fall into one or more of the CBS categories.
3. Establish the appropriate cost factors in constant dollars for each activity in the CBS, where constant dollars reflect the general purchasing power of the dollar at the time of decision (i.e., today). Relating costs in terms of constant dollars will allow for a direct comparison of activity levels from year to year prior to the introduction of inflationary cost factors, changes in price levels, economic effects of contractual agreements with suppliers, and so on, which can often cause some confusion in the evaluation of alternatives.
4. Within each cost category in the CBS, the individual cost elements are projected into the future on a year-to-year basis over the life cycle as applicable. The result should be a cost

- stream in constant dollars for the activities that are included.
- For each cost category in the CBS and for each applicable year in the life cycle, introduce the appropriate inflationary factors, economic effects of learning curves, changes in price levels, and so on. The modified values constitute a new cost stream and reflect realistic costs as they are anticipated for each year of the life cycle (i.e., expected 1996 costs in 1996, 1997 costs in 1997, etc.). These costs may be used directly in the preparation of future budget requests, since they reflect the actual dollar needs anticipated for each year in the life cycle.
  - Summarize the individual cost streams by major categories in the CBS and develop a top-level cost profile.

Results from the foregoing sequence of steps are presented in Fig. 188.4. First, it is possible and often beneficial to evaluate the cost stream for individual activities of the life cycle such as research and development, production, operation and support, and so on. Second, these individual cost streams may be shown in the context of the total cost spectrum. Finally, the total cost profile may be viewed from the standpoint of the logical flow of activities and the proper level and timely expenditure of dollars. The profile in Fig. 188.4 represents a budgetary estimate of future resource needs.

**Figure 188.4** Development of life-cycle cost profiles.

When dealing with two or more alternative system configurations, each will include different levels of activity, different design approaches, different logistic support requirements, and so on. No two systems alternatives will be identical. Thus, individual profiles will be developed for each alternative and ultimately compared on an equivalent basis utilizing the economic analysis techniques found in earlier chapters. Figure 188.5 illustrates life-cycle cost profiles for several alternatives.

**Figure 188.5** Life-cycle cost profiles of alternatives.

## 188.6 Summary

---

Life-cycle costing is applicable in all phases of system design, development, production, construction, operational use, and logistic support. Cost emphasis is created early in the life cycle by establishing quantitative cost factors as "design to" requirements. As the life cycle progresses, cost is employed as a major parameter in the evaluation of alternative design configurations and in the selection of a preferred approach. Subsequently, cost data are generated based on established design and production characteristics and used in the development of life-cycle cost projections. These projections, in turn, are compared with the initial requirements to determine the degree of compliance and the necessity for corrective action. In essence, life-cycle cost evolves from a series of rough estimates to a relatively refined methodology and is employed as a management tool for decision-making purposes.

### Defining Terms

**Cost breakdown structure (CBS):** A framework for defining life-cycle costs, and it provides the communications link for cost reporting, analysis, and ultimate cost control.

**Design-to-cost (DTC):** A concept that may be adopted to establish cost as a system or product design constraint, along with performance, effectiveness, capacity, accuracy, size, weight, reliability, maintainability, supportability, and others.

**Life-cycle cost (LCC):** All costs associated with the product or system as anticipated over the defined life cycle.

**Life-cycle cost analysis (LCCA):** A systematic analytical process for evaluating various alternative courses of action with the objective of choosing the best way to employ scarce resources.

**Life-cycle cost profile (LCCP):** A budgetary estimate of future resource needs over the life cycle.

A Final Note

### Hans J. Thamhain

*Bentley College*

For most organizations, resources are limited. The ability to select and fund the best projects with the highest probability of success is crucial to an organization's ability to survive and prosper in today's highly competitive environment. Project selections, necessary in virtually every business area, cover activities ranging from product developments to organizational improvements, customer contracts, R&D activities, and bid proposals. Evaluation and selection methods support two principal types of decisions:

1. Judging the chances of success for one proposed project
2. Choosing the best project among available alternatives

Although most decision processes evaluate projects in terms of cost, time, risks and benefits, such as shown in [Table 189.1](#), it is often extremely difficult, if not impossible, to define a meaningful aggregate measure for ranking projects regarding business success, technical risks, or profit. Managers can use traditional, purely rational selection processes toward "right," "successful," and "best" only for a limited number of business situations. Many of today's complex project evaluations require the integration of both analytical and judgmental techniques to be meaningful.

**Table 189.1** Typical Criteria for Project Evaluation and Selection

---

The criteria relevant to the evaluation and selection of a particular project depend on the specific project type and business situation such as project development, custom project, process development, industry and market. Typically, evaluation procedures include the following criteria:

- Development cost
- Development time
- Technical complexity

- Risk
- Return on investment
- Cost benefit
- Product life cycle
- Sales volume
- Market share
- Project business follow-on
- Organizational readiness and strength
- Consistency with business plan
- Resource availability
- Cash flow, revenue, and profit
- Impact on other business activities

Each criterion is based on a complex set of parameters and variables.

---

Although the literature offers a great variety of project selection procedures, each organization has its own special methods. Approaches fall into one of three principal classes:

1. Primarily quantitative and rational approaches
2. Primarily qualitative and intuitive approaches
3. Mixed approaches, combining both quantitative and qualitative methods

## 189.1 Quantitative Approaches to Project Evaluation and Selection

---

Quantitative approaches are often favored to support project evaluation and selections if the decisions require economic justification. Supported by numeric measures for simple and effective comparison, ranking, and selection, they help to establish quantifiable norms and standards and lead to repeatable processes. However, the ultimate usefulness of these methods depends on the assumption that the decision parameters—such as cash flow, risks, and the underlying economic, social, political, and market factors—can actually be quantified. Typically, these quantitative techniques are effective decision support tools if meaningful estimates of capital expenditures and future revenues can be obtained and converted into net present values for comparison. [Table 189.2](#) shows the cash flow of four project options to be used for illustrating the quantitative methods described in this chapter.

**Table 189.2** Cash Flow of Four Project Options or Proposals\*

End of Year	Do-Nothing Option P1	Project Option P2	Project Option P3	Project Option P4
0	0	–1000	–2000	–5000
1	0	200	1500	1000
2	0	200	1000	1500
3	0	200	800	2000
4	0	200	900	3000
5	0	200	1200	4000

Net cash flow	0	0	+3400	+7 500
NPV <sub>IN</sub> = 5	0	-242	+2153	+3 192
NPV <sub>IN</sub> = ∞	0	+1000	+9904	+28 030
ROI <sub>IN</sub> = 5	0	20%	54%	46%
CB = ROI <sub>NPV</sub>   $n = 5$	0	67%	108%	164%
$N_{PBP}   i = 0$	0	5	1.5	3.3
$N_{NPV}   i$	0	7.3	5	3.8

\*Assuming an MARR of  $i = 10\%$

*Note:* The first line of negative numbers represents the initial investment at the beginning of the life cycle.

## Net Present Value (NPV) Comparison

This method uses discounted cash flow as the basis for comparing the relative merit of alternative project opportunities. It assumes that all investment costs and revenues are known and that economic analysis is a valid singular basis for project selection.

We can determine the *net present value* (NPV) of a single revenue, stream of revenues, and/or costs expected in the future.

*Present worth* of a single revenue or cost (often called annuity,  $A$ ) occurring at the end of period  $n$  and subject to an effective interest rate  $i$  (sometimes referred to as discount rate or **minimum attractive rate of return, MARR**) can be calculated as:

$$PW(A | i, n) = A \frac{1}{(1 + i)^n} = PW_n$$

*Net present value* of a series of revenues or costs,  $A_n$ , over  $N$  periods of time is as follows:

$$NPV(A_n | i, N) = \sum_{n=1}^N A_n \frac{1}{(1 + i)^n} = \sum_{n=1}^N PW_n$$

[Table 189.2](#) applies these formulas to four project alternatives, showing the most favorable 5-year net present value of \$3192 for project option P4. (There are three special cases of net present value: (1) for a uniform series of revenues or costs over  $N$  periods,  $NPV(A_n | i, N) = A[(1+i)^N - 1]/i(1+i)^N$ ; (2) for an annuity or interest rate  $i$  approaching zero,  $NPV = A \times N$ ; and (3) for the revenue or cost series to continue forever,  $NPV = A/i$ .)

## Return-on-Investment Comparison

Perhaps one of the most popular measures for project evaluation is the *return on investment* (ROI):

$$ROI = \frac{\text{Revenue } (R) - \text{Cost } (C)}{\text{Investment } (I)}$$

It calculates the ratio of net revenue over investment. In its simplest form it entails the revenue on a year-by-year basis relative to the initial investment (for example, project option 2 in [Table 189.2](#) would produce a 20% ROI). Although this is a popular measure, it does not permit a comparative evaluation of alternative projects with fluctuating costs and revenues. In a more sophisticated way we can calculate the average ROI per year

$$\overline{\text{ROI}}(A_n, I_n \mid N) = \left[ \sum_{n=1}^N \frac{A_n}{I_n} \right] / N$$

and compare it to the minimum attractive rate of return. All three project options, P2, P3 and P4, compare favorably to the MARR of 10%, with project P3 yielding the highest average return on investment of 54%. Or we can calculate the net present value of the total ROI over the project lifecycle, also known as *cost-benefit* (CB). This is an effective measure of comparison, especially for fluctuating cash flows. ([Table 189.2](#) shows project 3 with the highest 5-year  $\text{ROI}_{\text{NPV}}$  of 108%.)

$$\text{ROI}_{\text{NPV}}(A_n, I_n \mid i, N) = \left[ \sum_{n=1}^N \text{NPV}(A_n \mid i, N) \right] / \left[ \sum_{n=1}^N \text{NPV}(I_n \mid i, N) \right]$$

## Pay-Back Period (PBP) Comparison

Another popular figure of merit for comparing project alternatives is the *payback period* (PBP). It indicates the time period of net revenues required to return the capital investment made on the project. For simplicity, *undiscounted* cash flows are often used to calculate a quick figure for comparison, which is quite meaningful if we deal with an initial investment and a steady stream of net revenue. However, for fluctuating revenue and/or cost streams, the net present value must be calculated for each period individually and cumulatively added up to the "break-even point" in time,  $N_{\text{PBP}}$ , when the net present value of revenue equals the investment.

$$\sum_{n=1}^N \text{NPV}(A_n \mid i) \geq \sum_{n=1}^N \text{NPV}(I_n \mid i)$$

## Pacifico and Sobelman Project Ratings

The previously discussed methods of evaluating projects rely heavily on the assumption that technical and commercial success is ensured and all costs and revenues are predicable. Because of these limitations, many companies have developed their own special procedures for comparing project alternatives. Examples are the *project rating factor* (PR), developed by Carl Pacifico for

assessing chemical products, and the *project value factor* ( $z$ ), developed by Sidney Sobelman for new product selections:

$$PR = \frac{pT \times pC \times R}{TC} \qquad z = (P \times T_{LC}) - (C \times T_D)$$

Pacifico's formula is in essence an ROI calculation adjusted for risk. It includes probability of technical success [ $.1 < pT < 1.0$ ], probability of commercial success [ $.1 < pC < 1.0$ ], total net revenue over project life cycle [ $R$ ], and total capital investment for product development, manufacturing setup, marketing, and related overheads [ $TC$ ]. The Sobelman formula is a modified cost-benefit measure. It takes into account both the development time and the commercial life cycle of the product. It includes average profit per year [ $P$ ], estimated product life cycle [ $T_{LC}$ ], average development cost per year [ $C$ ], and years of development [ $T_D$ ].

## Limitations of Quantitative Methods

Although quantitative methods of project evaluation have the benefit of producing relatively quickly a measure of merit for simple comparison and ranking, they also have many limitations, as summarized in [Table 189.3](#).

**Table 189.3** Comparison of Quantitative and Qualitative Approaches to Project Evaluation

Quantitative Methods	Qualitative Methods
Benefits:	Benefits:
Simple comparison, ranking, selection	Search for meaningful evaluation metrics
Repeatable process	Broad-based organizational involvement
Encourages data gathering and measurability	Understanding of problems, benefits, opportunities
Benchmarking opportunities	Problem solving as part of selection process
Programmable	Broad knowledge base
Input to sensitivity analysis and simulation	Multiple solutions and alternatives
	Multifunctional involvement leads to buy-in
	Risk sharing
Limitations:	Limitations:
Many success factors are nonquantifiable	Complex, time-consuming process
Probabilities and weights change	Biases via power and politics
True measures do not exist	Difficult to proceduralize or repeat
Analysis and conclusions are often misleading	Conflict- and energy-intensive
Methods mask unique problems and opportunities	Do not fit conventional decision processes
Stifle innovative decision making	Intuition and emotion dominates over facts
Lack people involvement, buy-in, commitment	Justify wants over needs
Do not deal well with multifunctional issues and dynamic situations	Lead to more fact finding than decision making
Pressure to act prematurely	

## 189.2 Qualitative Approaches to Project Evaluation and Selection

---

Especially for project evaluations involving complex sets of business criteria, the narrowly focused quantitative methods must often be supplemented by broad-scanning; intuitive processes; and collective, multifunctional decision making, such as Delphi, nominal group technology, brainstorming, focus groups, sensitivity analysis, and benchmarking. Each of these techniques can either be used by itself to determine the best, most successful, or most valuable option, or be integrated into an analytical framework for *collective multifunctional decision making*, which is discussed in the next section.

### Collective Multifunctional Evaluations

Collective multifunctional evaluations rely on subject experts from various functional areas for collectively defining and evaluating broad **project success** criteria, employing both quantitative and qualitative methods. The first step is to define the specific organizational areas critical to project success and to assign expert evaluators. For a typical product development project, these organizations may include R&D, engineering, testing, manufacturing, marketing, product assurance, and customer services. These function experts should be given the time necessary for the evaluation. They also should have the commitment from senior management for full organizational support. Ideally, these evaluators should have the responsibility for ultimate project implementation, should the project be selected.

The next step is for the evaluation team to define the factors that appear critical to the ultimate success of the projects under evaluation and arrange them into a concise list that includes both quantitative and qualitative factors. A mutually acceptable scale must be worked out for scoring the evaluation criteria. Studies of collective multifunctional assessment practices show that simplicity of scales is crucial to a workable team solution. Three types of scale have produced most favorable results in field studies: (1) 10-point scale, ranging from +5 = most favorable to -5 = most unfavorable; (2) 3-point scale, +1 = favorable, 0 = neutral or can't judge, -1 = unfavorable; and (3) 5-point scale, A = highly favorable, B = favorable, C = marginally favorable, D = most likely unfavorable, F = definitely unfavorable. **Weighing of criteria** is not recommended for most applications, since it complicates and often distorts the collective evaluation.

Evaluators score first individually all of the factors that they feel qualified to make an expert judgment on. Collective discussions follow. Initial discussions of project alternatives, their markets, business opportunities, and technologies involved are usually beneficial but not necessary for the first round of the evaluation process. The objective of this first round of expert judgments is to get calibrated on the opportunities and challenges presented. Further, each evaluator has the opportunity to recommend (1) actions needed for better assessment of project, (2) additional data needed, and (3) suggestions that would enhance project success and the evaluation score. Before meeting at the next group session, agreed-on action items and activities for improving the decision process should be completed. With each iteration the function-expert meetings are enhanced with more refined project data. Typically, between three and five iterations are required before a project

selection can be finalized.

## 189.3 Recommendations for Effective Project Evaluation and Selection

---

Effective evaluation and selection of project opportunities is critical to overall project success. With increasing complexities and dynamics of the business environment, most situations are too complex to use simple economic models as the sole basis for decision making. To be effective, project evaluation procedures should include a broad spectrum of variables for defining the project value to the organization.

Structure, discipline, and manageability can be designed into the selection process by grouping the evaluation variables into four categories: (1) consistency and strength of the project with the business mission, strategy, and plan; (2) multifunctional ability to produce the project results, including technical, cost, and time factors; (3) success in the customer environment; and (4) economics, including profitability. Modern **phase management** and **stage-gate processes** provide managers with the tools for organizing and conducting project evaluations effectively. [Table 189.4](#) summarizes suggestions that may help managers to effectively evaluate projects for successful implementation.

**Table 189.4** Suggestions for Effective Project Evaluation and Selection

---

1. **Seek out relevant information.** Meaningful project evaluations require relevant quality information. The four categories of variables can provide a framework for establishing the proper metrics and detailed data gathering.
2. **Take top-down look; detail comes later.** Detail is less important than information relevancy and evaluator expertise. Don't get hung up on lack of data during the early phases of the project evaluation. Evaluation processes should iterate. It does not make sense to spend a lot of time and resources gathering perfect data to justify a "no-go" decision.
3. **Select and match the right people.** Whether the project evaluation consists of a simple economic analysis or a complex multifunctional assessment, competent people from those functions critical to the overall success of the project(s) should be involved.
4. **Success criteria must be defined.** Deciding on a single project or choosing among alternatives, evaluation criteria must be defined. They can be quantitative, such as ROI, or qualitative, such as the probability of winning a contract. In either case, these evaluation criteria should cover the true spectrum of factors affecting success and failure of the project(s). Only functional experts, discussed in point 3, are qualified to identify these success criteria. Often, people from outside the company, such as vendors, subcontractors, or customers, must be included in this expert group.
5. **Strictly quantitative criteria can be misleading.** Be aware of evaluation procedures based only on quantitative criteria (ROI, cost, market share, MARR, etc). The input data used to calculate these criteria are likely based on rough estimates and are often unreliable.

Evaluations based on predominately quantitative criteria should at least be augmented with some expert judgment as a "sanity check."

6. **Condense criteria list.** Combine evaluation criteria, especially among the judgmental categories, to keep the list manageable. As a goal, try to stay within 12 criteria.
  7. **Communicate.** Facilitate communications among evaluators and functional support groups. Define the process for organizing the team and conducting the evaluation and selection process.
  8. **Ensure cross-functional cooperation.** People on the evaluation team must share a strategic vision across organizational lines. They also must sense the desire of their host organizations to support the project if selected for implantation. The purpose, goals, and objectives of the project should be clear, along with the relationship to the business mission.
  9. **Don't lose the big picture.** As discussions go into detail during the evaluation, the team should maintain a broad perspective. Two global judgment factors can help to focus on the big picture of project success: (1) overall benefit-to-cost perception and (2) overall risk-of-failure perception. These factors can be recorded on a ten-point scale: -5 to +5. This also leads to an effective two-dimensional graphic display of competing project proposals.
  10. **Do your homework between iterations.** As project evaluations are most likely conducted progressively, action items for more information, clarification, and further analysis surface. These action items should be properly assigned and followed up, thereby enhancing the quality of the evaluation with each consecutive iteration.
  11. **Stimulate innovation.** Senior management should foster an innovative ambience for the evaluation team. Evaluating complex project situations for potential success or failure involves intricate sets of variables, linked among organization, technology, and business environment. It also involves dealing with risks and uncertainty. Innovative approaches are required to evaluate the true potential of success for these projects. Risk sharing by senior management, recognition, visibility, and a favorable image in terms of high priority, interesting work, and importance of the project to the organization have been found strong drivers toward attracting and holding quality people to the evaluation team and gaining their active and innovative participation in the process.
  12. **Manage and lead.** The evaluation team should be chaired by someone who has the trust, respect, and leadership credibility with the team members. Further, management can positively influence the work environment and the process by providing some procedural guidelines, charters, visibility, resources, and active support to the project evaluation team.
- 

## A Final Note

Effective project evaluation and selection requires a broad-scanning process that can deal with the risks, uncertainties, ambiguities, and imperfections of data available at the beginning of a project cycle. It also requires managerial leadership and skills in planning, organizing, and

communicating. Above all, evaluation team leaders must be social architects in unifying the multifunctional process and its people. They must share risks and foster an environment that is professionally stimulating and strongly linked with the support organizations eventually needed for project implementation. This is an environment that is conducive to **cross-functional** communication, cooperation, and integration of the intricate variables needed for effective project evaluation and selection.

## Defining Terms

**Cross-functional:** Actions that span organizational boundaries.

**Minimum attractive rate of return (MARR):** The annual net revenue produced on average by projects in an organization as a percentage of their investments. Sometimes MARR is calculated as company earnings over assets.

**Net worth:** Discounted present value of a future revenue or cost.

**Phase management:** Projects are broken into natural implementation phases, such as development, production, and marketing, as a basis for project planning, integration, and control. Phase management also provides the framework for *concurrent engineering* and *stage-gate processes*.

**Project success:** A comprehensive measure, defined in both quantitative and qualitative terms, that includes economic, market, and strategic objectives.

**Stage-gate process:** Framework for executing projects within predefined stages (see also **phase management**) with measurable deliverables (*gate*) at the end of each stage. The gates provide the review metrics for ensuring successful transition and integration of the project into the next stage.

**Weighing of criteria:** A multiplier associated with specific evaluation criteria.

### 190.5 Project Management Using CPM

## John L. Richards

*University of Pittsburgh*

The purpose of this chapter is to describe the three-step, iterative decision-making process of planning, scheduling, and controlling with the critical path method (CPM). CPM is a network-based analytical tool that models a project's activities and their predecessor/successor interrelationships. **Planning** is the development of a **work breakdown structure (WBS)** of the project's activities. **Scheduling** is the calculation of **activity parameters** by doing a forward and a backward pass through the network. **Controlling** is the monitoring of the schedule during project execution by **updating** and **upgrading**, as well as the modifying of the schedule to achieve feasibility and optimality using cost duration analysis and critical resource analysis.

## 190.1 Planning the Project

---

Project planning requires the development of a work breakdown structure, which then becomes the basis for a network model of the project. This model can then be used to evaluate the project by comparing regular measures of performance.

### Project Performance Measures

The three common performance measures in project management are *time*, *cost*, and *quality*. The overall objective is to accomplish the project in the least time, at the least cost, with the highest quality. Individually, these objectives conflict with each other. Thus, the manager must seek an overall solution by trading off among them. Further, since the overall project is defined by the

activities that must be done, the overall project duration, cost, and quality will be determined by the individual activity times, cost, and quality levels.

## Activity Time-Cost Trade-off

For a specified quality level for a given activity, the manager initially selects that combination of resources (labor, equipment, and material) that accomplishes that particular activity at the least cost. This is the *normal* duration on an *activity time-cost trade-off curve* (Fig. 190.1). Thus, since each activity is to be done at its least cost, the overall project will be done at the least total cost. However, in order to reduce an activity's duration, the activity cost must increase. For example, one can work overtime at premium rates or use more expensive equipment, which increases cost, in order to reduce an activity's duration. *Crash* is the shortest possible activity duration, no matter how high the cost. The inverse relationship between time and cost yields curves with negative slopes.

**Figure 190.1** Activity time-cost trade-off curve. The normal time (point a) is the least cost/longest activity duration. The crash time (point b) is the least activity duration/highest cost.

## Activity Interrelationships

There are two possible relationships between a pair of activities in a project network: (1) one must immediately precede the other (*predecessor*), or (2) one must immediately follow the other (*successor*). If there is no predecessor/successor relationship, the activities may be done simultaneously. These predecessor/successor relationships are derived from absolute constraints such as physical/technological, safety, and legal factors; or imposed constraints such as the selection of resources, methods, and financing. The manager should initially incorporate

relationships derived only from absolute constraints. Relationships derived from imposed constraints should be added only as necessary to achieve feasibility. This approach to predecessor/successor relationships yields the least constrained project network initially.

The basic predecessor/successor relationship is finish to start with no lead or lag. However, more sophisticated models allow three other types: start to finish, finish to finish, and start to start. In addition, each of the four could have a lead time or a lag time. Thus there are twelve possible ways to describe a particular predecessor/successor relationship.

## Work Breakdown Structure

The work breakdown structure (WBS) of a project is the listing of all the individual activities that make up the project, their durations, and their predecessor/successor relationships. It should be the least costly and least constrained method of executing the project, that is, normal durations and absolute constraints only. Therefore, if the schedule resulting from this initial WBS is feasible, then it is also optimal. If, however, the schedule is infeasible because of time and/or resource considerations, then the manager would want to achieve feasibility with the least additional cost. (Scheduling and feasibility/optimality are discussed in later sections).

There are three approaches to developing a WBS: (1) by physical components, (2) by process components, and (3) by spatial components. *Physical components* model a constructed product (e.g., build wall). *Process components* model a construction process (e.g., mix concrete). *Spatial components* model a use of time or space (e.g., order steel or cure concrete). No matter which of the three approaches is used to define a particular activity in a WBS, each should be described by an action verb to distinguish an activity from an event. (Note: There can be special activities in a WBS that involve time only and no cost, such as curing concrete. There can also be dummy activities for logic only that have no time or cost.)

A project's WBS must be developed to an appropriate level of detail. This means that activities must be broken down sufficiently to model interrelationships among them. Also, a standard time period (hour, shift, day, week, etc.) must be chosen for all activities. An appropriate WBS will have a reasonable number of activities and reasonable activity durations.

**Example 190.1¾ Work Breakdown Structure.** Table 190.1 shows a WBS for constructing a backyard in-ground swimming pool with vinyl liner. Note that a time period of days was selected for all activities.

**Table 190.1** WBS of Swimming Pool Construction

Activity ID	Duration	Description	Immediate Predecessors
A101	10	Order and deliver filtration equipment	—
A202	5	Order and deliver liner/piping	—
B301	4	Excavate for pool	—
B202	3	Install liner/piping	A202, B301
B102	2	Install filtration	A101

		equipment	
C301	2	Fill pool	B202
B401	5	Construct deck	B202
C302	2	Connect and test system	C301, B102
B501	3	Landscape area	B401

---

## 190.2 Scheduling the Project

---

The critical path method of project scheduling is based upon a network model that can be analyzed by performing a forward and a backward pass to calculate activity parameters.

### CPM Network Models

There are two types of network models: activity oriented and event oriented. Both types have nodes connected by arrows that model events (points in time) and activities (processes over time).

#### Activity-Oriented Diagram

The activity-oriented diagram is also called an *arrow diagram* (ADM) or *activity on arrow* (AOA). The activities are the arrows, and the events are the nodes. Dummy activities (depicted as dashed arrows) may be required to correctly model the project for logic only. Activity identification is by node pairs (node  $i$  to node  $j$ ). This was the original diagramming method. It is easy to visualize but difficult to draw.

#### Event-Oriented Diagram

The event-oriented diagram is also called a *precedence diagram* (PDM), *activity on node* (AON), or *circle network*. The activities are the nodes, and the events are the ends of arrows. There are no dummies. All arrows are for logic only, which also allows for modeling the twelve types of activity interrelationships discussed earlier. This diagramming method is easier to draw and well suited to computer use. Although developed after AOA, the AON has become the preferred method.

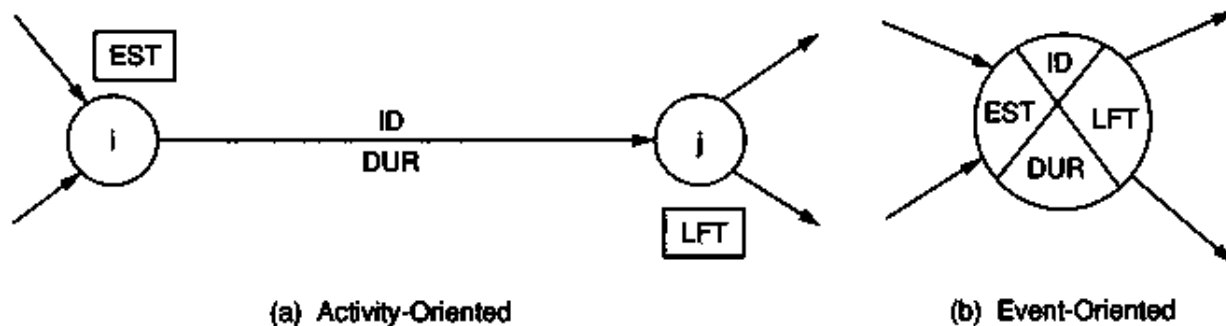

### CPM Network Calculations

There are three steps in the manual analysis of a CPM network that determine the activity parameters. The forward pass determines the *earliest start time* (EST) of each activity. The backward pass determines the *latest finish time* (LFT) of each activity. The other times, the *earliest finish time* (EFT) and the *latest start time* (LST), and the floats, *total float* (TF) and *free float* (FF), are then determined from a table. The calculation process is the same for either type of network (ADM or PDM). Before beginning the process, one needs to establish a time convention—beginning of time period or end of time period. The example in this chapter uses beginning of time period, thus the first day is day one. (The end-of-time-period convention would begin with day zero.)

## Forward Pass

To determine the EST of an activity, one compares all the incoming arrows—that is, the *heads* of arrows—choosing the *largest* earliest event time. The comparison is made among all the immediately preceding activities by adding their ESTs and respective durations. The process begins at the start node (the EST being zero or one) and proceeds to the end node, taking care that all incoming arrows get evaluated. At the completion of the forward pass, one has determined the overall project duration. The ESTs can be placed on diagrams as shown in [Fig. 190.2](#).

**Figure 190.2** Activity graphical models. The activity identification (ID) and duration (DUR) are from the WBS. The EST and LFT are calculated from the forward and backward passes, respectively.

## Backward Pass

The backward pass begins at the end node with the overall project duration (which is the LFT) and proceeds to the start node. This process determines the LFT for each activity by comparing the outgoing arrows—that is, the *tails* of arrows—choosing the *smallest* latest event time. The comparison is made among all the immediately succeeding activities by subtracting their durations from their respective LFTs. At the completion of the backward pass one should calculate the original project start time. The LFTs can be placed on diagrams as shown in [Fig. 190.2](#).

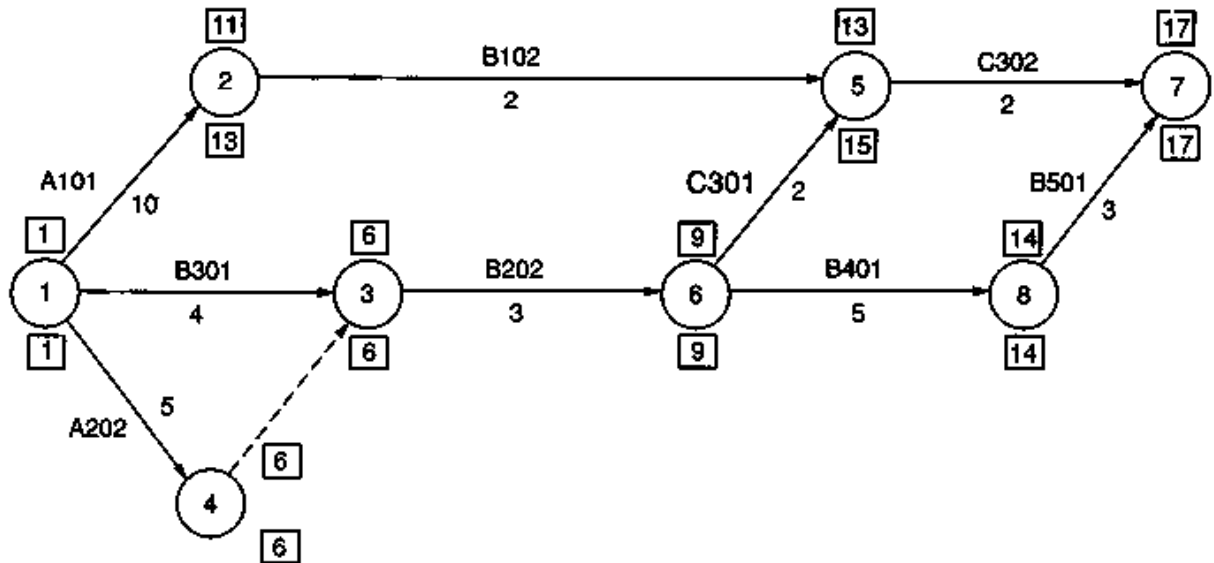

## Floats

The other two times (EFT and LST) and floats (TF and FF) are determined in a tabular format using the following relationships: (1)  $EFT = EST + \text{duration}$ , (2)  $LST = LFT - \text{duration}$ , (3)  $TF = LFT - EFT$  or  $TF = LST - EST$ , and (4)  $FF = EST \text{ (of following activities)} - EFT$ . Activities with a  $TF = 0$  are on a **critical path**. There may be more than one critical path in a network. If the duration of any critical path activity is increased, the overall project duration will increase. Activities with  $TF > 0$  may be increased without affecting the overall project duration. On the other hand, free float is that amount of total float that can be used by the activity without affecting any other activities. If  $TF$  equals 0, then  $FF$  equals 0, necessarily. Free float may be some, all, or no portion of total float.

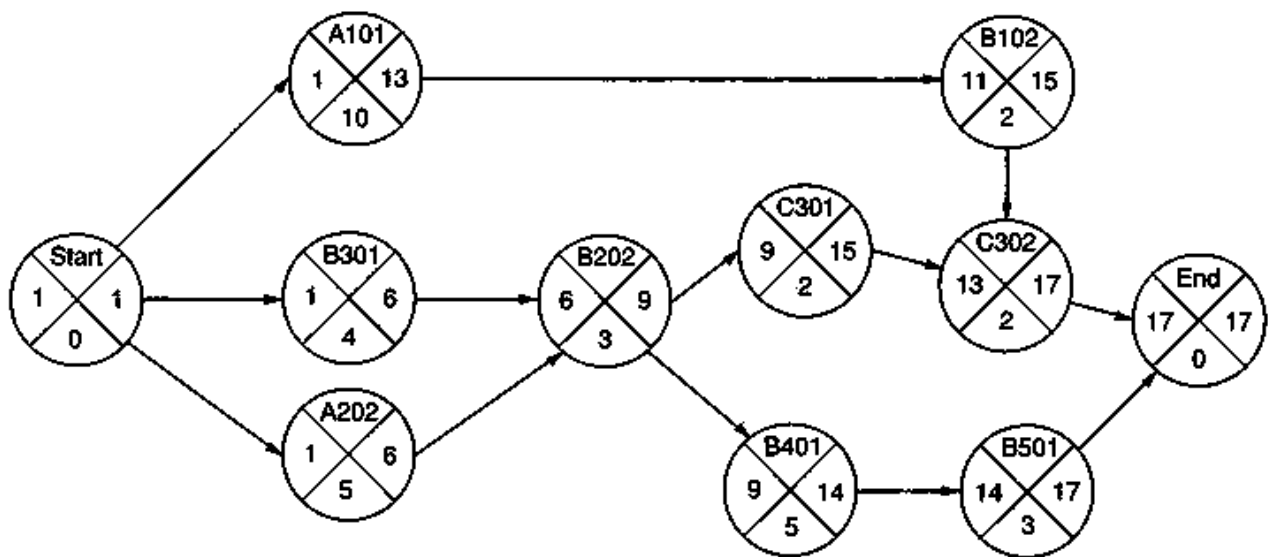

**Example 190.2 CPM Scheduling.** This example continues with the project introduced in [Table](#)

190.1. The CPM calculations for the forward and backward passes are shown in Fig. 190.3 for both network types. Table 190.2 lists all the times and floats.

**Figure 190.3** CPM network calculations (forward and backward passes). The overall project duration was determined to be 16 days ( $17 - 1 = 16$ ).

(a) Activity-Oriented Network (ADM or AOA)  
Note that activity 4-3 is a dummy and is also on the critical path.

(b) Event-Oriented Network (PDM or AON)  
Note that implied start and end nodes are shown with zero durations.

**Table 190.2** Activity Times and Floats

Activity ID	Duration	EST	EFT	LST	LFT	TF	FF
A101	10	1	11	3	13	2	0
A202*	5	1	6	1	6	0	0
B102	2	11	13	13	15	2	0
B202*	3	6	9	6	9	0	0
B301	4	1	5	2	6	1	1
B401*	5	9	14	9	14	0	0
B501*	3	14	17	14	17	0	0
C301	2	9	11	13	15	4	2
C302	2	13	15	15	17	2	2

\* Activities on critical path.

## 190.3 Controlling the Project

CPM-based project management provides the tools to control time and money in a dynamic and hierarchical project environment during project execution.

### Managing Time and Money

Computerized project management systems can provide a variety of informational outputs for use in managing a project. These include network diagrams showing activity interrelationships, bar charts showing activity durations, tabular listings showing activity parameters, and profiles showing cash flows or resource utilization during the project.

### Hierarchical Management

Project management generally occurs in a multiproject environment with multiple time parameters and multiple managerial levels. Multiple project models integrate cash flow and resource profiles of several projects. Multiple calendar models allow activities to be done at different time frames (for example, some may be done five days per week, others seven days per week). Project management information systems can provide summary information for upper-level management and detailed information for workers in the field.

### Managing the Schedule

The project schedule is a dynamic managerial tool that changes during project execution.

#### Updating the Schedule

As the project proceeds the schedule should be **updated** at periodic intervals to reflect actual activity progress. Such updates can incorporate percent complete, remaining durations, and actual start and end dates for each activity. The updates can be the basis for evaluating overall project objectives (time and money) and for making progress payments. After any update, a new schedule calculation must be done to determine new times and floats.

## Upgrading the Schedule

Any change to an existing schedule either by changing a planned duration or an activity relationship is a schedule **upgrade**. A schedule upgrade can occur either prior to start of the project, or any time during the project, based on new information. After any upgrade a new schedule calculation must be done to determine new times and floats.

## Managing the Floats

A negative total float indicates that the project will overrun the stated completion date. A positive ( $> 0$ ) total float indicates that the project will be completed earlier than the stated completion date. A particular network will generally have many different total float paths, including negative ones if it is behind schedule, and no zero ones if it is ahead of schedule.

Free float indicates that amount of time an activity can be manipulated without affecting any other activity (and therefore the project as a whole). When managing the floats, one would want to use free float before total float. Once total float is used, the activity becomes part of a new critical path.

The use of the floats can be a difficult contractual issue among the parties. It is a good idea to decide beforehand how the floats can be used. Otherwise the issue may be part of a delay claim at the completion of the project.

**Example 190.3%4Updating and Upgrading.** This example continues with the project introduced in [Table 190.1](#) and originally scheduled in [Table 190.2](#).

1. *Updating.* Assume that it is the beginning of day 6 and that activity B301 is done, and A101 has 9 days left and A202 has 2 days left. These updated durations are used in [Fig. 190.3](#) to recalculate activity times and floats as shown in [Table 190.3](#). Notice that a second critical path has developed and that the overall project duration has been extended two days.
2. *Upgrading.* Now assume that immediately after updating, the duration for activity C302 gets changed to three days and B401 must precede it. These upgrades could be incorporated into a revised [Fig. 190.3](#) (not shown) to recalculate another set of activity times and floats as shown in [Table 190.4](#). Notice that there is now only one critical path and the overall project duration has been extended another day to day 20.

**Table 190.3** Activity Times and Floats (Update)

Activity ID	Duration	EST	EFT	LST	LFT	TF	FF
A101*	9	6	15	6	15	0	0
A202*	2	6	8	6	8	0	0
B102*	2	15	17	15	17	0	0
B202*	3	8	11	8	11	0	0
B301	0	—	—	—	—	—	—
B401*	5	11	16	11	16	0	0

B501*	3	16	19	16	19	0	0
C301	2	11	13	15	17	4	4
C302*	2	17	19	17	19	0	0

\* Activities on critical path.

**Table 190.4** Activity Times and Floats (Upgrade)

Activity ID	Duration	EST	EFT	LST	LFT	TF	FF
A101*	9	6	15	6	15	0	0
A202	2	6	8	7	9	1	0
B102*	2	15	17	15	17	0	0

C302*	3	17	20	17	20	0	0

\* Activities on critical path.

## 190.4 Modifying the Project Schedule

Project planning, scheduling, and controlling is an iterative decision-making process. It is highly unlikely for an initial schedule to be both feasible and optimal in the first iteration. Likewise, it is highly unlikely that the actual project execution will match the original project plan exactly. Therefore, one must know how to modify the project schedule in order to achieve feasibility and optimality. The modification process involves either changing activity duration, changing activity relationships, or both.

### Cost Duration Analysis

**Cost duration analysis (CDA)** utilizes activity time/cost trade-off curves (discussed earlier) in order to compress the overall project schedule. The objective is to buy back each time unit in the cheapest possible manner until the desired completion date is reached (feasibility). Only activities on a critical path need be reduced. The others with positive float simply have the float reduced. The problem can become very complex in a large network with multiple critical paths where the incremental additional costs for the activities are different.

### Critical Resource Analysis

The approach to **critical resource analysis (CRA)** is different from CDA in that it seeks to extend the overall project duration the least amount in order to resolve resource conflicts (i.e., achieve feasibility). CRA can be viewed from one of two perspectives: (1) constrained resources—staying

below a specified limit, or (2) resource leveling—selecting a constant limit. The solution approach for either is the same. The problem is one of ordering (predecessor/successor relationships) those activities that have resource conflicts during the same time period. The pairwise comparison of all such activities in a large network with many critical resources presents a huge combinatorial problem. The only viable solution approaches are based upon heuristic decision rules. (A simple rule could be that the predecessor activity should be the one with the smaller LST.)

## Combined CDA and CRA

Combining CDA and CRA to achieve a feasible and optimal schedule is virtually impossible for all but the simplest networks. Although the CDA problem does have rigorous mathematical solutions, they are not incorporated in most commercial software. On the other hand, the software generally does incorporate heuristic-based solutions for the CRA problem. Therefore, one should use the software in an interactive decision-making manner.

**Example 190.4<sup>3/4</sup> CDA and CRA.** Assume that after the upgrade as shown in [Table 190.4](#), it is decided that the desired completion date is day 19, and also that activities B102 and B401 cannot be done simultaneously because of insufficient labor. Further, assume that B401 can be reduced from 5 days to 3 days at an additional cost of \$200 per day and that C302 can be reduced from 3 days to 2 days at an additional cost of \$400.

**Solution.** The solution approach to this problem is to work two cases: (1) B102 precedes B401, and compress B401 and/or C302 if they lie on a critical path, and (2) B401 precedes B102, and again compress B401 and/or C302. Case 1 would yield an overall project duration of 25 days, and one can readily see that it is impossible to reduce it 6 days (one can only gain a total of 3 days from activities B401 and C302). Case 2 (B401 precedes B102) yields an overall project duration of 21 days, with both B401 and C302 on the same critical path. One should choose the least expensive method to gain one day—that is, change B401 to 4 days for \$200. This yields a project duration of 20 days and an additional critical path. Therefore, reducing B401 another day to 3 days does not get the project to 19 days. Instead, the more expensive activity (C302) must be reduced from 3 to 2 days for \$400. The answer to the problem, then, is B401 goes from 5 to 4 days for \$200, and C302 goes from 3 to 2 days for \$400. Thus, the overall project duration is compressed from 21 to 19 days from a total additional cost of \$600.

## 190.5 Project Management Using CPM

---

CPM was first developed in the late 1950s by the Remington Rand Corporation and the DuPont Chemical Company. Since then, many software manufacturers have developed sophisticated computer-based management information systems using CPM. In addition to performing the CPM calculations discussed in this chapter, such systems can provide data for creating the historical file of an ongoing project, for developing estimating information for a future project, and for performance evaluation of both the project and the participating managers. CPM has even become a well-accepted means for analyzing and resolving construction disputes.

The successful use of CPM as a managerial tool involves not only the analytical aspects discussed in this chapter, but also the attitude that is displayed by those using it in actual practice. If CPM is used improperly as a weapon, rather than as a tool, there will be project management failure. Therefore, successful project management must include positive team building among all project participants, along with the proper application of the critical path method.

## Defining Terms

**Activity parameters:** The activity times (EST, EFT, LFT, and LST) and activity floats (TF and FF) calculated in the scheduling step.

**Controlling:** The third step in the interactive decision-making process, which monitors the accomplishments of the project by updating and upgrading and seeks feasibility and optimality by cost duration analysis and critical resource analysis.

**Cost duration analysis (CDA):** Reducing durations of selected activities in the least costly manner in order to achieve a predetermined project completion date.

**Critical path (CP):** String of activities from start to finish that have zero total float. There may be more than one CP, and the CPs may change after an update or upgrade.

**Critical resource analysis (CRA):** Sequencing selected activities in such a manner as to minimize the increase in project duration in order to resolve resource conflicts among competing activities.

**Planning:** The first step in the interactive decision-making process, which determines the work breakdown structure.

**Scheduling:** The second step in the interactive decision-making process, which determines the activity parameters by a forward and a backward pass through a network.

**Update:** Changing remaining activity durations due to progress only, then rescheduling.

**Upgrade:** Changing activity durations and interrelationships due to new information only, then rescheduling.

**Work breakdown structure (WBS):** Listing of the individual activities that make up the project, their durations, and their predecessor/successor relationships.

**Carol I. Bordas**

*Thorp, Reed & Armstrong*

The origins of U.S. intellectual property law—which includes patents, copyrights, and trademarks—can be traced to medieval England. Letters Patent were issued by the king of England under the Statute of Monopolies in 1623 to confer the exclusive privilege of working or making a new manufacture for a 14-year term to the true and first inventor. In 1710 the Statute of Anne was enacted to both limit and create copyright monopolies in the publishing industry. Within the medieval guilds, individual artisans such as jewelers placed marks on their products in order that a purchaser could identify the source of their product.

Today a patent, copyright, trademark, or license can be used to protect intellectual property rights. For example, a computer program used in a process for manufacturing a new drug can be protected by a patent, a copyright, a trademark, and a license. A patent can be obtained for the process of manufacturing and to protect the use of the computer program in manufacturing the drug. A trademark can be used to identify the origin of the computer program. A copyright is created in the source code, which prevents the copying of the program. The owner of the copyrighted program can enter into a license agreement in which the licensee can distribute and reproduce the program in return for royalties payable to the licensor-owner.

### 191.1 Patents

---

A patent can be viewed as a contract between the inventor and the government in which the government grants the inventor the right to exclude others from making, using, or selling the invention in exchange for the inventor fully disclosing the invention to the public. In order for an

inventor to obtain patent protection in the U.S., an inventor must apply for a patent and be granted a U.S. Letters Patent by the U.S. Patent and Trademark Office (USPTO). Three types of patents are granted by the USPTO. Utility patents are granted for processes, machines, manufactures, compositions of matter, and any improvements thereof that are useful, new, and unobvious to one of ordinary skill in the art. Design patents are granted for any new, original, and ornamental design of an article of manufacture. Plant patents are granted for any distinct and new variety of plant, including those asexually produced and those found in an uncultivated state.

A utility patent application includes (1) a description of the invention, (2) at least one **claim** that defines the boundaries of protection sought by the patent applicant, and (3) any drawings necessary to understand the invention. The description of the invention must disclose the **best mode** of practicing the invention known by the inventor at the time of filing the patent application.

In order to be granted a U.S. patent the utility patent application must describe an invention that is useful, novel, and unobvious. The invention is novel if the invention was conceived and reduced to practice before any **prior art**. The invention is unobvious if the invention would have been unobvious to one of ordinary skill in the art at the time of the filing of the patent application in view of the prior art [Chisum, 1994]. If the invention was patented or described in any printed publication, in public use, or on sale in the U.S. more than one year before the U.S. patent application filing date, the inventor is barred by law from being granted a patent.

There is no one patent that can grant worldwide protection for an invention. Generally, if an inventor seeks to protect an invention in a foreign country, the inventor must apply for a patent in that specific country. The term of a patent in a foreign country usually extends for 20 years from the filing date of the patent application.

Patent infringement is the making, using, or selling of a patented invention during the term of the patent without the permission of the owner of the patent. The patented invention is defined by the claims of the patent. When every element recited in a claim of the patent or an equivalent of the element is present in an accused infringing device, direct infringement is established.

## 191.2 Copyrights

---

A copyright prohibits others from copying a work. Copyrights protect expressions of original work of authorship fixed in a tangible medium. Works that can be copyrighted include literary works, musical works, dramatic works, pantomimes and choreographic works, pictorial, graphic and sculptural works, motion pictures and other audiovisual works, sound recordings, and architectural works [Nimmer, 1993]. Copyrights only protect nonfunctional artistic features of a work.

The owner of a copyright has the exclusive right to reproduce the work, prepare **derivative works** based on the work, distribute the work, perform the work, and display the work. Generally, the owner of the copyright is the author of the work unless the work was specially commissioned or was produced in the scope of the employment of the author, in which case the employer is the author and owner of the copyright and the work is considered a work for hire.

Because a copyright is created at the moment the expression is fixed in a tangible medium, a copyright need not be registered with the U.S. Copyright Office to be valid. However, if the copyright is registered within five years of the publication of the work, the copyright is presumed to be valid. Further, registration is a prerequisite for a copyright infringement action in the courts.

A federal copyright registration application includes (1) an application form, (2) a filing fee, and (3) two **best editions** of the copyrighted work. The copyright application is examined for completeness, consistency of information, and appropriateness of subject matter. The term of a registered copyright is generally the life of the author plus 50 years. If the copyrighted work is a joint work, the term of the copyright is the length of the last surviving author plus 50 years. If the work is a work for hire, the copyright term is 75 years from the first publication or 100 years from the year of creation, whichever comes first.

To establish infringement one must prove both (1) ownership of a valid copyright, and (2) copying of the original work. Copying is usually established if a substantial similarity between the accused work and the copyrighted work exists, and if the accused infringer had access to the copyrighted work. Although copyright notice is no longer required, if notice is affixed to the infringed work, innocent infringement cannot be successfully claimed by the infringing party. Copyright notice consists of the word "Copyright" or an abbreviation thereof, the year of publication, and the name of the copyright owner. One can affix copyright notice to a work that has not been registered with the Copyright Office.

The U.S. is a signatory to the **Berne Convention** and as a result copyrighted works of U.S. citizens enjoy the same copyright protection as other signatory countries accord their nationals.

## 191.3 Trademarks

---

A trademark is a badge of origin placed on goods to signify the origin of the goods. A word or several words, a symbol, a color, or a scent can be utilized as a trademark. A mark that is distinguishable from other trademarks should be chosen in order that there is no confusion as to the origin of the goods [McCarthy, 1994].

Trademarks can be registered in the USPTO as well as with a state agency within each of the 50 states and in most foreign countries. In the case of federal trademark registration, the trademark must be based on actual use or based on a *bona fide intent to use* the trademark. A federal trademark registration will generally be granted unless the trademark (1) includes immoral, deceptive, or scandalous matter; (2) includes a flag or coat of arms or other insignia of a municipality or nation; (3) includes a name, portrait, or signature identifying a particular living individual without written consent of the individual or includes the name, signature, or portrait of a deceased president of the U.S. during the life of his widow without written consent; (4) resembles a trademark registered in the USPTO that when used can cause confusion; or (5) when used with the goods is merely descriptive, deceptively misdescriptive, geographically misdescriptive, or is merely a surname. However, if the applicant for registration can establish that the mark is distinctive such that the public identifies the mark with the goods—that is, the mark gains **secondary meaning**<sup>3/4</sup> then the mark's being descriptive, misdescriptive, or a surname will not prevent the applicant from obtaining a trademark registration.

An application for federal trademark registration based on actual use consists of (1) a written application that includes a description of the goods to which the mark is affixed, the date of first use of the mark in commerce, and the manner in which the mark is used; (2) a drawing of the mark; (3) **specimens** of the mark as it is used on the goods; and (4) the filing fee. An application based on an intent to use contains all of these four items except that the date of the first use of the

trademark and the description of the manner of use of the mark are both supplied to the USPTO within six months after a trademark has been allowed. A trademark registration has a term of ten years from the date of registration, which can be renewed for ten-year periods indefinitely.

Trademark infringement is established if a likelihood of confusion between the accused mark and the protected trademark exists. The following are some factors that are considered when determining if there is a likelihood of confusion: similarity of marks, similarity of goods, or similarity and character of markets.

## 191.4 Licenses

---

A license can be granted by the owner of a patent, a copyright, or a trademark to permit another to use the owner's exclusive rights while retaining title in exchange for a **royalty**. A patent owner can license others to make, use, and sell the invention. The three rights can be licensed separately or in combination with one another. In other words the patent owner can license the right to make the invention to one individual and license the rights to use and sell the invention to a second individual. The license may be exclusive or nonexclusive. An **exclusive license** prohibits the patent owner from licensing the same right to another [Lipscomb, 1993], whereas a nonexclusive license permits the patent owner to enter into the same nonexclusive licensing agreement with more than one individual. Other terms and conditions can be added to a patent licensing agreement, such as a territory restriction.

A copyright license must take the form of a nonexclusive license. An exclusive license of the copyright owner's rights, even if limited in time and place, is considered a transfer of copyright ownership. An owner of a copyright can enter into a nonexclusive license agreement that grants any of the exclusive rights of a copyright. For example, the licensee can be granted the right to reproduce the copyright subject matter and distribute the copyrighted work but not display the copyrighted work. One joint author does not need the permission of the other joint author when he enters into a nonexclusive license agreement of his copyright. No recordation requirement for nonexclusive copyright licenses exists.

For a trademark license to be valid the licensor must control the nature and the quality of the goods or services sold under the mark. Controlling the use of the licensed trademark ensures that the licensee's goods are of equal quality to that of the licensor. If the quality of the goods and services designated by the trademark are changed, then the public could be deceived. If proper quality control is not practiced by the licensee, the trademark could be considered abandoned by the licensee.

# LOCOMOTIVE STEAM-ENGINE FOR RAIL AND OTHER ROADS

## John Ruggles

Patented July 13, 1836 #1

This was the first patent awarded under the Act of 1836. Ruggles, a senator from Maine, was in charge of the research leading up to the drafting of this sweeping legislation.

Because no examination of "prior art" was made between 1802 and 1836, patents were granted, in effect, to whomever applied. Patents were once again to be examined for novelty and usefulness. Specifications, drawings, and a model were to be furnished. The Patent Office was now a separate State Department bureau with a Commissioner and appointees to perform the necessary examinations and other clerical work. A sequential numbering system, still used today, made filing of the increasing number of patents easier and more coherent.

It seems more than a coincidence that Ruggles was awarded patent #1; perhaps it was in honor of his efforts to create the new patent system. He spent only one term in the Senate and returned to his law practice in Maine in 1841. (©1993, DewRay Products, Inc. Used with permission.)

## Defining Terms

- Berne Convention:** The Convention for the Protection of Literary and Artistic Works, signed at Berne, Switzerland, on 9 September 1986.
- Best edition:** The edition of a copyright work, published in the U.S. before the deposit, that the Library of Congress determines suitable.
- Best mode:** The specification must set forth the best mode contemplated by the inventor in carrying out the invention. The requirement is violated when the inventor knew of a superior method of carrying out the invention at the time of filing the application and concealed it.
- Claim:** An applicant must include one or more claims in a patent application that set forth the parameters of the invention. A claim recites a number of elements or limitations and covers only those inventions that contain all such elements and limitations.
- Derivative work:** A work based on one or more preexisting copyrighted works.
- Exclusive license:** A license that permits the licensee to use the patent, trademark, or copyright and prohibits another from using the patent, trademark, or copyright in the same manner.
- Prior art:** Those references that may be used to determine the novelty and nonobviousness of claimed subject matter in a patent application or a patent. Prior art includes all patents and publications.
- Royalty:** A payment to the owner of a patent, trademark, or copyright that is payable in proportion to the use of the owner's rights in the patent, trademark, or copyright.
- Secondary meaning:** A trademark acquires secondary meaning when the trademark is distinctive such that the public identifies the trademark with the goods. A descriptive trademark is protected only when secondary meaning is established. A generic trademark can never acquire secondary meaning.
- Specimen:** Trademark specimens consist of samples of promotional material bearing the trademark used for labeling of applicant's goods.

The Prodigy is a state-of-the-art type of cementless implant. The main material used in this total hip replacement (THR) is a high-strength cobalt chrome. A clinically proven porous coating called Porocoat® is used on the ball and stem of the Prodigy. Porocoat® allows bone and tissue matter to grow into the porous material and enables the THR to be cementless.

The Prodigy stem and cobalt chrome ball mate with a titanium Duraloc acetabular cup. This cup has a congruent interface between the metal shell and a polyethylene liner. This liner is made of a polymer called Hylamer®, which offers enhanced creep resistance, increased wear resistance, improved resistance to oxidation, and superior quality control. THE PLACEMENT OF SECTIONS ON MATERIALS and mathematics at the end of the *Engineering Handbook* is symbolic of their general relationships to the full range of engineering disciplines. The central role of materials in the engineering profession is further suggested by the basic definition provided by the Accreditation Board for Engineering and Technology (ABET): "Engineering is the profession in which a knowledge of the mathematical and natural sciences gained by study, experience, and practice is applied with judgment to develop ways to utilize, economically, the *materials* and forces of nature for the benefit of mankind" [emphasis mine].

This section covers a wide range of issues dealing with engineering materials. First, the key properties of solids are reviewed. Representative tables of property data are provided to give general guidance in the selection of the appropriate materials for a given engineering design. We cannot provide a comprehensive source of data in this relatively brief introduction. We do give, however, a sense of the relative performance of various representative materials and references to more comprehensive sources such as *The CRC Materials Science and Engineering Handbook*.

Properties guide us in the selection of materials, but an increasingly important role for engineers is to evaluate problems which arise when the materials selected for an engineering application prove to be inadequate. In this regard, the systematic methodology of failure analysis is reviewed. Fracture mechanics and nondestructive testing play central roles in failure analysis. The growing body of work in this field is laying the foundation for failure prevention in future engineering designs.

It is important to remember that materials of significance to engineering are not all in the solid state. A discussion of liquids and gases outlines the nature of key fluids involved in a wide variety

of engineering systems.

Among the most intriguing applications of engineering materials are those used in biology and medicine. These "biomaterials" range from the polymers used in the cardiovascular system to the metallic alloys used in orthopedic joint replacement.

- 192.5 Thermal Properties
- 192.6 Chemical Properties
- 192.7 Electrical and Optical Properties

**James F. Shackelford**

*University of California, Davis*

The term *materials science and engineering* refers to that branch of engineering dealing with the processing, selection, and evaluation of solid-state materials [Shackelford, 1992]. As such, this is a highly interdisciplinary field. This chapter reflects the fact that engineers outside of the specialized field of materials science and engineering largely need guidance in the selection of materials for their specific applications. A comprehensive source of property data for engineering materials is available in *The CRC Materials Science and Engineering Handbook* [Shackelford *et al.*, 1994]. This brief chapter will be devoted to defining key terms associated with the properties of engineering materials and providing representative tables of such properties. Because the underlying principle of the fundamental understanding of solid-state materials is the fact that atomic- or microscopic-scale structure is responsible for the nature of materials properties, we shall begin with a discussion of structure, which will be followed by a discussion of the importance of specifying the chemical composition of commercial materials. These discussions will be followed by the definition of the main categories of material properties.

## 192.1 Structure

---

A central tenet of materials science is that the behavior of materials (represented by their **properties**) is determined by their structure on the atomic and microscopic scales [Shackelford, 1992]. Perhaps the most fundamental aspect of the structure-property relationship is to appreciate the basic skeletal arrangement of atoms in **crystalline** solids. Table 192.1 illustrates the fundamental possibilities, known as the 14 **Bravais lattices**. All crystalline structures of real materials can be produced by "decorating" the unit cell patterns of Table 192.1 with one or more atoms and repetitively stacking the unit cell structure through three-dimensional space.

**Table 192.1** The Fourteen Bravais Lattices

## 192.2 Composition

The properties of commercially available materials are determined by chemical composition as

well as structure [Shackelford, 1992]. As a result, extensive numbering systems have been developed to label materials, especially metal **alloys**. Table 192.2 gives an example for gray cast irons.

**Table 192.2** Composition Limits of Selected Gray Cast Irons (%)

UNS	SAE Grade	C	Mn	Si	P	S
F10004	G1800	3.40 to 3.70	0.50 to 0.80	2.80 to 2.30	0.15	0.15
F10005	G2500	3.20 to 3.50	0.60 to 0.90	2.40 to 2.00	0.12	0.15
F10009	G2500	3.40 min	0.60 to 0.90	1.60 to 2.10	0.12	0.12
F10006	G3000	3.10 to 3.40	0.60 to 0.90	2.30 to 1.90	0.10	0.16
F10007	G3500	3.00 to 3.30	0.60 to 0.90	2.20 to 1.80	0.08	0.16

## 192.3 Physical Properties

Among the most basic and practical characteristics of engineering materials are their physical properties. Table 192.3 gives the **density** of a wide range of materials in units of  $\text{Mg/m}^3$  ( $= \text{g/cm}^3$ ), whereas Table 192.4 gives the **melting points** for several common metals and ceramics.

**Table 192.3** Density of Selected Materials ( $\text{Mg/m}^3$ )

Metal		Ceramic		Glass		Polymer	
Ag	10.50	$\text{Al}_2\text{O}_3$	3.97–3.986	$\text{SiO}_2$	2.20	ABS	1.05–1.07
Al	2.7	BN (cub)	3.49	$\text{SiO}_2$ 10 wt% $\text{Na}_2\text{O}$	2.291	Acrylic	1.17–1.19

## 192.4 Mechanical Properties

Central to the selection of materials for structural applications is their behavior in response to mechanical loads. A wide variety of mechanical properties are available to help guide materials selection [Shackelford *et al.*, 1994]. The most basic of the mechanical properties are defined in terms of the **engineering stress** and the **engineering strain**. The engineering stress,  $\sigma$ , is defined as

$$\sigma = P/A_o \quad (192.1)$$

where  $P$  is the load on the sample with an original (zero stress) cross-sectional area  $A_o$ . The engineering strain,  $\varepsilon$ , is defined as

$$\varepsilon = [l - l_o]/l_o = \Delta l/l_o \quad (192.2)$$

where  $l$  is the sample length at a given load and  $l_o$  is the original (zero stress) length. The maximum engineering stress that can be withstood by the material during its load history is termed the *ultimate tensile strength*, or simply **tensile strength**, TS. An example of the tensile strength for

selected wrought (meaning "worked," as opposed to cast) aluminum alloys is given in [Table 192.5](#) . The "stiffness" of a material is indicated by the linear relationship between engineering stress and engineering strain for relatively small levels of load application. The **modulus of elasticity**,  $E$ , also known as **Young's modulus**, is given by the ratio

$$E = \sigma / \varepsilon \quad (192.3)$$

[Table 192.6](#) gives values of Young's modulus for selected compositions of glass materials. The "ductility" of a material is indicated by the percent elongation at failure ( $= 100 \times \varepsilon_{\text{failure}}$  ), representing the general ability of the material to be plastically (i.e., permanently) deformed. The percent elongation at failure for selected polymers is given in [Table 192.7](#).

**Table 192.5** Tensile Strength of Selected Wrought Aluminum Alloys

Alloy	Temper	TS (MPa)
1050	0	76
1050	H16	130

#### ALUMINUM IN HISTORY

Original aluminum pellets shown on a page of hand-written minutes from a company meeting, circa 1890.

More than 7000 years ago, potters in ancient Persia made their strongest pots and bowls from a

clay that contained large amounts of a compound of aluminum and oxygen we know today as alumina. The Persians couldn't have known about aluminum, because it is not found in nature as a metal. However, they did discover one of the advantages that makes certain aluminum compounds so useful in ceramics today; it made their pots durable.

Three thousand years later, the Egyptians and Babylonians were using other aluminum compounds. Physicians used alum (a mixture of aluminum and sulphates) to control bleeding. Aluminum compounds also were used by these people for fabric dyes and cosmetics. The first man to produce aluminum metal may have been a Chinese chemist. Scientists believe this discovery took place about 300 B.C. A belt, decorated with aluminum, was found in the tomb of a Chinese general, known to have died about then.

However, the secret of producing aluminum in quantity eluded the world's finest scientists until the 19th century. The British chemist, Sir Humphry Davy, established the existence of aluminum in 1808 but failed to extract it from the ore. In 1825, the Danish physicist, Hans Christian Oersted, succeeded in producing a few droplets of aluminum.

For many years, a German chemist named Friederich (or Friedrich) Wöhler concentrated on improving Oersted's method. The credit for bringing aluminum out of the laboratory and into the marketplace (though its applications at the time were quite costly and specialized) generally goes to the French metallurgist, Henri Sainte-Claire DeVille. Improving on Wöhler's process, DeVille was able, in 1854, to produce aluminum the size of marbles. By 1869, DeVille was producing nearly two tons a year, and the price had dropped from \$545 to \$17 per pound. But aluminum was still far too costly to be made in quantities that people could afford.

It began to look as if only the wealthy would be able to purchase products made of aluminum. Aluminum tableware was used to serve honored guests at the French Court. Denmark's King Christian X wore an aluminum crown. In 1884, a six-pound aluminum cap was used to crown the top of the Washington Monument. It was probably the biggest single chunk of aluminum in the world at the time. The cap is still in place today.

As more aluminum was produced, scientific interest in the metal increased. Finally, in 1886, two inventors in their twenties, American Charles Martin Hall and Frenchman Paul L. T. Héroult, independently and within two months of each other, discovered a practical process for making aluminum inexpensively. That process is still used around the world today. ## 192.5 Thermal Properties

---

Many applications of engineering materials depend on their response to a thermal environment. The **thermal conductivity**,  $k$ , is defined by **Fourier's law**:

$$k = -[dQ/dt]/[A(dT/dx)] \quad (192.4)$$

where  $dQ/dt$  is the rate of heat transfer across an area  $A$  due to a temperature gradient  $dT/dx$ . It is also important to note that the dimensions of a material will, in general, increase with temperature.

Increases in temperature lead to greater thermal vibration of the atoms and an increase in average separation distance of adjacent atoms. The **linear coefficient of thermal expansion**,  $\alpha$ , is given by

$$\alpha = dl/l dT \quad (192.5)$$

with  $\alpha$  having units of  $\text{mm}/(\text{mm}^\circ\text{C})$ . Examples of thermal conductivity and thermal expansion coefficient for alloy cast irons are given in [Table 192.8](#).

**Table 192.8** Thermal Conductivity and Thermal Expansion of Alloy Cast Irons

Alloy	Thermal Conductivity W/(m K)	Thermal Expansion Coefficient $\text{mm}/(\text{m}^\circ\text{C})$
Low-C white iron	22 <sup>a</sup>	12 <sup>b</sup>
Martensitic nickel-chromium iron	30 <sup>a</sup>	8 – 9 <sup>b</sup>

## 192.6 Chemical Properties

A wide variety of data are available to characterize the nature of the reaction between engineering materials and their chemical environments [[Shackelford et al., 1994](#)]. Perhaps no such data are more fundamental and practical than the **electromotive force series** of metals shown in [Table 192.9](#). The voltage associated with various half-cell reactions in standard aqueous environments are arranged in order, with the materials associated with more anodic reactions tending to be corroded in the presence of a metal associated with a more cathodic reaction.

**Table 192.9** Electromotive Force Series of Metals

Metal	Potential (V)	Metal	Potential (V)	Metal	Potential (V)
Anodic or Corroded End					
Li	–3.04	Al	–1.70	Pb	–0.13
Rb	–2.93	Mn	–1.04	H	0.00
K	–2.92	Zn	–0.76	Cu	0.52
Ba	–2.90	Cr	–0.60	Ag	0.80

Sr	-2.89	Cd	-0.40	Hg	0.85
Ca	-2.80	Ti	-0.33	Pd	1.0

## 192.7 Electrical and Optical Properties

To this point, we have concentrated on various properties dealing largely with the structural applications of engineering materials. In many cases the electromagnetic nature of the materials may determine their engineering applications. Perhaps the most fundamental relationship in this regard is **Ohm's law**, which states that the magnitude of current flow,  $I$ , through a circuit with a given resistance  $R$  and voltage  $V$  is related by:

$$V = IR \quad (192.6)$$

where  $V$  is in units of volts,  $I$  is in amperes, and  $R$  is in ohms. The resistance value depends on the specific sample geometry. In general,  $R$  increases with sample length,  $l$ , and decreases with sample area,  $A$ . As a result, the property more characteristic of a given material and independent of its geometry is **resistivity**,  $\rho$ , defined as

$$\rho = [RA]/l \quad (192.7)$$

The units for resistivity are ohm  $\cdot$  m (or  $\Omega \cdot \text{m}$ ). [Table 192.10](#) gives the values of electrical resistivity for various materials, indicating that metals typically have low resistivities (and correspondingly high electrical conductivities) and ceramics and polymers typically have high resistivities (and correspondingly low conductivities).

**Table 192.10** Electrical Resistivity of Selected Materials

Metal (Alloy Cast Iron)	$\rho$ ( $\Omega \cdot \text{m}$ )	Ceramic	$\rho$ ( $\Omega \cdot \text{m}$ )	Polymer	$\rho$ ( $\Omega \cdot \text{m}$ )
Low-C white cast iron	$0.53 \cdot 10^{-6}$	$\text{Al}_2\text{O}_3$	$> 10^{13}$	ABS	$2-4 \cdot 10^{13}$
Martensitic Ni-Cr iron	$0.80 \cdot 10^{-6}$	$\text{B}_4\text{C}$	$0.3-0.8 \cdot 10^{-2}$	Acrylic	$> 10^{13}$
High-Si iron	$0.50 \cdot 10^{-6}$	BN	$1.7 \cdot 10^{11}$	HDPE	$> 10^{15}$
High-Ni iron	$1.4-1.7 \cdot 10^{-6}$	BeO	$> 10^{15}$	Nylon 6/6	$10^{12}-10^{13}$
Ni-Cr-Si iron	$1.5-1.7 \cdot 10^{-6}$	MgO	$1.3 \cdot 10^{13}$	Phenolic	$10^7-10^{11}$
High-Al iron	$2.4 \cdot 10^{-6}$	SiC	$1-1 \cdot 10^{10}$	Polyacetal	$10^{13}$
Medium-Si ductile iron	$0.58-0.87 \cdot 10^{-6}$	$\text{Si}_3\text{N}_4$	$10^{11}$	Polypropylene	$> 10^{15}$
High-Ni (20%) ductile iron	$1.02 \cdot 10^{-6}$	$\text{SiO}_2$	$10^{16}$	PTFE	$> 10^{16}$

Selected data from Shackelford, J. F., Alexander, W., and Park, J. S. (Eds.) 1994. *CRC Materials Science and Engineering Handbook*, 2nd ed. CRC Press, Boca Raton, FL.

An important aspect of the electromagnetic nature of materials is their optical properties. Among the most fundamental optical characteristics of a light-transmitting material is the **index of refraction**,  $n$ , defined as

$$n = v_{\text{vac}}/v \quad (192.8)$$

where  $v_{\text{vac}}$  is the speed of light in vacuum (essentially equal to that in air) and  $v$  is the speed of light in a transparent material. The index of refraction for a variety of polymers is given in [Table 192.11](#).

**Table 192.11** Refractive Index of Selected Polymers

Polymer	$n$
Acrylic	1.485–1.500
Cellulose Acetate	1.46–1.50
Epoxy	1.61
HDPE	1.54
Polycarbonate	1.586
PTFE	1.35
Polyester	1.50–1.58
Polystyrene	1.6
SAN	1.565–1.569
Vinylidene chloride	1.60–1.63

Data compiled by J. S. Park from Lynch, C. T. (Ed.) 1975. *CRC Handbook of Materials Science, Volume 3*. CRC Press, Inc., Boca Raton, FL; and ASM. 1988. *Engineered Materials Handbook, Volume 2, Engineering Plastics*. ASM International, Metals Park, OH.

## Defining Terms

**Alloy:** Metal composed of more than one element.

**Bravais lattice:** One of the 14 possible arrangements of points in three-dimensional space.

**Crystalline:** Having constituent atoms stacked together in a regular, repeating pattern.

**Density:** Mass per unit volume.

**Electromotive force series:** Systematic listing of half-cell reaction voltages.

**Engineering strain:** Increase in sample length at a given load divided by the original (stress-free) length.

**Engineering stress:** Load on a sample divided by the original (stress-free) area.

**Fourier's law:** Relationship between rate of heat transfer and temperature gradient.

**Index of refraction:** Ratio of speed of light in vacuum to that in a transparent material.

**Linear coefficient of thermal expansion:** Material parameter indicating dimensional change as a function of increasing temperature.

**Melting point:** Temperature of transformation from solid to liquid upon heating.

**Ohm's law:** Relationship between voltage, current, and resistance in an electrical circuit.

**Property:** Observable characteristic of a material.

**Resistivity:** Electrical resistance normalized for sample geometry.

**Tensile strength:** Maximum engineering stress during a tensile test.

**Thermal conductivity:** Proportionality constant in Fourier's law.

**Young's modulus (modulus of elasticity):** Ratio of engineering stress to engineering strain for relatively small levels of load application.

Radiographic Testing • Ultrasonic Testing • Other Methods of Nondestructive Testing

[193.5 Engineering Design for Failure Prevention](#)**James F. Shackelford**

*University of California, Davis*

Failure analysis and prevention are important, practical considerations relative to the applications of materials in engineering design [ASM, 1986]. This chapter begins by exploring the various types of failures that can occur. There is now a well-established, systematic methodology for the analysis of failures of engineering materials. Beyond **failure analysis** as a "postmortem" examination, the related issue of **failure prevention** is equally important as the basis for avoiding future disasters. Fracture mechanics provides a powerful technique for both analyzing failures and modifying engineering designs for the prevention of future failures. Similarly, nondestructive testing serves as one set of techniques for a comprehensive analysis of failures, as well as a primary strategy for the prevention of future failures, especially in the identification of critical flaws. The two primary techniques on which we will focus are radiographic testing (typically using X rays) and ultrasonic testing.

The issues of failure analysis and failure prevention are taking on increasing levels of importance with the growing awareness of the responsibilities of the professional engineer. Ethical and legal demands for the understanding of engineering failures and the prevention of such future catastrophes are moving the field of materials science and engineering into a central role in the broader topic of engineering design.

---

## 193.1 Types of Failures

---

A wide spectrum of failure modes has been identified. To illustrate the range of these types of failures, we will begin with a brief description of several of the most common failures in structural metals.

*Ductile fracture* is observed in a large number of the failures occurring in metals due to overload—that is, simply taking a material beyond the elastic limit, beyond its ultimate tensile strength, and, subsequently, to fracture. The microscopic result of ductile fracture is a characteristic

"dimpled" fracture surface morphology.

*Brittle fracture* is characterized by rapid crack propagation without significant plastic deformation on a macroscopic scale. The cleavage texture of a brittle fracture surface comes from both *transgranular* fracture, involving the cleavage of microstructural grains, and *intergranular* fracture, occurring by crack propagation between adjacent grains.

*Fatigue failure* is the result of cyclic stresses that would, individually, be well below the yield strength of the material. The fatigue mechanism of slow crack growth gives a distinctive "clamshell" fatigue fracture surface.

*Corrosion-fatigue failure* is due to the combined actions of a cyclic stress and a corrosive environment. In general, the fatigue strength (or fatigue life at a given stress) of the metal will be decreased in the presence of an aggressive, chemical environment.

*Stress-corrosion cracking* (SCC) is another combined mechanical and chemical failure mechanism in which a noncyclic tensile stress (below the yield strength of the metal) leads to the initiation and propagation of fracture in a relatively mild chemical environment. Stress-corrosion cracks may be intergranular, transgranular, or a combination thereof.

*Wear failure* encompasses a broad range of relatively complex surface-related damage phenomena. Both surface damage and wear debris can constitute "failure" of materials intended for sliding contact applications.

*Liquid erosion failure* is a special form of wear damage in which a liquid, rather than another solid, is responsible for the removal of material. Liquid-erosion damage typically results in a pitted or honeycomb-like surface region.

*Liquid-metal embrittlement* is another form of material failure caused by a liquid. In this case the solid loses some degree of ductility or fractures below its yield stress in conjunction with its surface being wetted by a lower-melting-point liquid metal. This failure mode occurs in specific solid-liquid metal combinations.

*Hydrogen embrittlement* is perhaps the most notorious form of catastrophic failure in high-strength steels. A few parts per million of hydrogen dissolved in these materials can lead to fine "hairline" cracks and a loss of ductility. A variety of commercial environments serve as sources of hydrogen gas that, in turn, dissociates into atomic hydrogen, which can readily diffuse into the alloy.

*Creep and stress-rupture failures* can occur above about one-half the absolute melting point of an alloy. *Creep* is defined as plastic deformation over an extended period of time under a fixed load. Failure of this type can occur near room temperature for many polymers and certain low-melting-point metals, such as lead, but may occur above 1000°C in many ceramics and certain high-melting-point metals, such as the superalloys.

*Complex failures* are those in which the failure occurs by the sequential operation of two distinct fracture mechanisms. An example would be initial cracking due to stress-corrosion cracking and, then, ultimate failure by fatigue after a cyclic load is introduced simultaneously with the removal of the corrosive environment. The possibility of such sequences should always be considered when conducting a failure analysis.

## 193.2 Failure Analysis Methodology

---

A systematic sequence of procedures has been developed for the analysis of the failure of an engineering material. Although the specific methodology will vary with the specific failure, the principal components of the investigation and analysis are given in [Table 193.1](#). This specific set of components is that given in the *ASM Handbook* volume on failure analysis and prevention [[ASM, 1986](#)]. Because of the general utility of **nondestructive testing** for failure prevention as well as failure analysis, the subject is covered in detail later in this chapter. **Fracture mechanics** is the general analysis of the failure of structural materials with preexisting flaws. This subject will be discussed separately in the next section. In regard to failure analysis methodology, fracture mechanics has provided a quantitative framework for evaluating structural reliability.

**Table 193.1** Principal Components of Failure Analysis Methodology

---

Collection of background data and samples
Preliminary examination of the failed part
Nondestructive testing
Mechanical testing
Selection, preservation, and cleaning of fracture surfaces
Macroscopic (1 to 100 × ) examination of fracture surfaces
Microscopic (> 100 × ) examination of fracture surfaces
Application of fracture mechanics
Simulated-service testing
Analyzing the evidence, formulating conclusions, and writing the report

---

## 193.3 Fracture Mechanics

---

The **fracture toughness**,  $K_{Ic}$ , is the most widely used material parameter associated with fracture mechanics [[Shackelford, 1992](#)] and is, in general, of the simple form

$$K_{Ic} = \sigma_f (\pi a)^{1/2} \quad (193.1)$$

where  $\sigma_f$  is the overall applied stress at failure and  $a$  is the length of a surface crack (or one-half the length of an internal crack). Fracture toughness has units of  $\text{MPa}\cdot\text{m}^{1/2}$ . Typical values of fracture toughness for various metals and alloys range between 20 and 200  $\text{MPa}\cdot\text{m}^{1/2}$ . Values of fracture toughness for ceramics and glass are typically in the range of 1 to 9  $\text{MPa}\cdot\text{m}^{1/2}$ , values for polymers are typically 1 to 4  $\text{MPa}\cdot\text{m}^{1/2}$ , and values for composites are typically 10 to 60  $\text{MPa}\cdot\text{m}^{1/2}$ . Although Eq. (193.1) is widely used for predicting flaw-induced or "fast" fracture, one must keep in mind that the subscript  $I$  refers to "mode  $I$ " loading—that is, simple, uniaxial tension. Fortunately, mode  $I$  conditions predominate in most practical systems, and the wide use of  $K_{Ic}$  is justified. Another aspect of fracture mechanics is the relationship to fatigue and other mechanical phenomena in which flaw size increases incrementally prior to failure.

## 193.4 Nondestructive Testing

As with fracture mechanics, nondestructive testing can serve to analyze an existing failure or be used to prevent future failures [Bray and Stanley, 1989]. The dominant techniques within this field are radiography and ultrasonics.

### Radiographic Testing

X rays compose a portion of the electromagnetic spectrum. Although diffraction techniques allow dimensions on the order of the X-ray wavelength (typically less than one nanometer) to be determined, X radiography produces a "shadow graph" of the internal structure of a part with a much coarser resolution (typically on the order of 1 mm). The common chest X ray is a routine example of this technology. In industrial applications, X radiography is widely used for the inspection of castings and weldments.

A key factor in this test is the thickness of material through which the X-ray beam can penetrate. For a given material being inspected by a given energy X-ray beam, the intensity of the beam,  $I$ , transmitted through a thickness of material,  $x$ , is given by Beer's law:

$$I = I_0 e^{-\mu x} \quad (193.2)$$

where  $I_0$  is the incident beam intensity and  $\mu$  is the linear absorption coefficient for the material. The intensity is proportional to the number of photons in the beam and should not be confused with the energy of photons in the beam. The absorption coefficient is a function of the beam energy and of the elemental composition of the material. Experimental values for the linear absorption coefficient of iron as a function of energy are given in Table 193.2. The general trend is a steady drop in the magnitude of  $\mu$  with increasing beam energy until above 1 MeV, where  $\mu$  levels off. Below 1 MeV the absorption of the beam is due to mechanisms of photon absorption and photon scattering. Above 1 MeV, however, an additional absorption mechanism comes into play (electron-positron pair production).

**Table 193.2** Linear Absorption Coefficient of Iron as a Function of X-Ray Beam Energy

Energy (MeV)	$\mu$ (mm <sup>-1</sup> )
0.05	1.52
0.10	0.293
0.50	0.0662
1.00	0.0417
2.00	0.0334
4.00	0.0260

Selected data from Bray, D. E. and Stanley, R. K. 1989. *Nondestructive Evaluation*. McGraw-Hill, New York.

The dependence of the linear absorption coefficient on elemental composition is illustrated by the data of Table 193.3. The general trend of data is that  $\mu$  for a given beam energy increases with

atomic number. As a result, low–atomic-number metals such as aluminum are relatively transparent and high–atomic-number metals such as lead are relatively opaque.

**Table 193.3** Linear Absorption Coefficient of Various Elements for an X-Ray Beam with Energy = 100 keV (= 0.1 MeV)

Element	Atomic Number	$\mu$ (mm <sup>-1</sup> )
Titanium	22	0.124
Iron	26	0.293
Nickel	28	0.396
Copper	29	0.410
Zinc	30	0.356
Tungsten	74	8.15
Lead	82	6.20

Selected data from Bray, D. E. and Stanley, R. K. 1989. *Nondestructive Evaluation*. McGraw-Hill, New York.

## Ultrasonic Testing

X radiography was seen to be based on a portion of the electromagnetic spectrum with relatively short wavelengths in comparison to the visible region. Similarly, ultrasonic testing is based on a portion of the acoustic spectrum with frequencies above those of the audible range (20 to 20 000 cycles/second or Hz). Typical ultrasonic inspections are made in the 1 to 25 MHz range. A key distinction between X radiography and ultrasonic testing is that the ultrasonic waves are mechanical in nature and require a transmitting medium, whereas electromagnetic waves can be transmitted in a vacuum.

Whereas attenuation of the X-ray beam in the solid was a dominant consideration for X radiography, typical engineering materials are relatively transparent to ultrasonic waves. The key consideration for ultrasonic testing is the reflection of the ultrasonic waves at dissimilar material interfaces. The reflection coefficient,  $R$ , defined as the ratio of reflected beam intensity,  $I_r$ , to incident beam intensity,  $I_i$ , is given by

$$R = I_r/I_i = [(Z_2 - Z_1)/(Z_2 + Z_1)]^2 \quad (193.3)$$

where  $Z$  is the acoustic impedance, defined as the product of the material's density and velocity of sound, with the subscripts 1 and 2 referring to the two dissimilar materials on either side of the interface. The high degree of reflectivity by a typical flaw, such as an internal crack, is the basis for defect inspection. [Figure 193.1](#) illustrates a typical "pulse echo" ultrasonic inspection based on this principle. The oscillations in the figure represent voltage fluctuations in a piezoelectric transducer that is used to both send and detect the ultrasonic signal. The horizontal scale is proportional to time in a time frame of several microseconds. The initial pulse on the left is reflected back from a flaw and seen in the mid-range, with a small pulse on the right representing a reflection from the back side of the sample. The insert is a C-scan in which numerous adjacent A-scan pulses are viewed together to represent the spatial location of the flaw (impact damage in a NASA

graphite/epoxy wind tunnel blade). The dashed line corresponds to the displayed A-scan. The limitations of this method include the difficulty of applying the techniques in complex-shaped parts and the loss of information due to microstructural complexities such as porosity and precipitates.

**Figure 193.1** Typical ultrasonic pulse echo A-scan of a structural defect. (Ultrasonic imaging software provided courtesy of D. Bailey, McClellan Air Force Base.)

## Other Methods of Nondestructive Testing

A wide spectrum of additional methods are available in the field of nondestructive testing. The following four methods are among the most widely used for failure analysis and prevention.

*Eddy current testing* is a versatile technique for inspecting electrically conductive materials. The impedance of an inspection coil is affected by the presence of an adjacent test piece, in which alternating (eddy) currents have been induced by the coil. The net impedance is a function of the composition or geometry of the test piece. The popularity of eddy current testing is due to the convenient, rapid, and noncontact nature of the method. By varying the test frequency the method

can be used for both surface and subsurface flaws. Limitations include the qualitative nature and the need for an electrically conductive test piece.

*Magnetic-particle testing* is a simple, traditional technique widely used due to its convenience and low cost. Its primary limitation is the restriction to magnetic materials. (This is not as restrictive as one might initially assume, given the enormous volume of structural steels used in engineering.) The basic mechanism of this test involves the attraction of a fine powder of magnetic particles (Fe or  $\text{Fe}_3\text{O}_4$ ) to the "leakage flux" around a discontinuity such as a surface or near-surface crack.

*Liquid-penetrant testing* is, like magnetic-particle testing, an inexpensive and convenient technique for surface defect inspection. It is largely used on nonmagnetic materials for which magnetic-particle inspection is not possible. The basic mechanism for this method is the capillary action of a fine powder on the surface of a sample in which a high-visibility liquid has penetrated into surface defects. The limitations of this technique include the inability to inspect subsurface flaws and the loss of resolution on porous materials.

*Acoustic-emission testing* has assumed a unique role in failure prevention. This nondestructive test, in addition to being able to locate defects, can provide an early warning of impending failure due to those defects. In contrast to conventional ultrasonic testing, in which a transducer provides the source of ultrasound, acoustic-emission is the set of ultrasonic waves produced by defects within the microstructure of a material in response to an applied stress. With the material as the source of ultrasound, transducers serve only as receivers. In general, the rate of acoustic-emission events rises sharply just prior to failure. By continuously monitoring these emissions, the structural load can be removed in time to prevent that failure. The primary example of this preventative application is in the continuous surveillance of pressure vessels.

## 193.5 Engineering Design for Failure Prevention

---

Finally, it is important to note that engineering designs can be improved as a result of the application of concepts raised in sections 193.1 and 193.2—that is, failure analysis can lead to failure prevention. An example of this approach includes the avoidance of structural discontinuities that can serve as stress concentrators.

### Defining Terms

**Failure analysis:** The systematic examination of a failed engineering part to determine the nature of the failure.

**Failure prevention:** The application of the principles of failure analysis to prevent future catastrophes.

**Fracture mechanics:** Analysis of failure of structural materials with preexisting flaws.

**Fracture toughness:** Critical value of the stress-intensity factor at a crack tip necessary to produce catastrophic failure.

**Nondestructive testing:** A family of techniques for observing material flaws and characteristics without impairing the future usefulness of the part under inspection.

## 194.1 Viscosity

## 194.2 Thermal Conductivity

## 194.3 Heat Capacity

## 194.4 Vapor Pressure

**Bruce E. Poling***University of Toledo*

There are a number of thermodynamic and kinetic properties of gases and liquids that are important in engineering applications. Properties that are discussed in this chapter include viscosity, thermal conductivity, heat capacity, and vapor pressure. In the material that follows, a brief description of each of these four properties is given. However, engineers often do not want a description; rather, they want a number or an equation. The strategy that should be used to accomplish this latter task depends on the particular situation, but many features of this strategy are independent of the desired property. Thus, a general strategy is presented first.

For gases at low pressures and pure liquids, experimental data for many substances are available and have generally been correlated by equations and sometimes by nomographs. Many such correlations, summaries of data sources, and tabulations of values can be found in the references at the end of the chapter. The types of information available in the various references are summarized in Table 194.1. If information for a new compound or information at temperatures or pressures outside the range where experimental data have been measured is required, estimation methods such as those described in Reid *et al.* [1987] may be used. Reid *et al.* [1987] also presents recommended methods for finding properties for gases that cannot be considered ideal (at high pressure) and for mixtures of compounds.

**Table 194.1** Information Available in Various References

Reference Number <sup>a</sup>		1	2, 3	4	5	6, 7	8	9	10

## 194.1 Viscosity

The **viscosity** of a fluid is a measure of its thickness, or how easily it flows. The viscosity,  $\eta$ , of a substance is defined as the shear stress per unit area divided by the velocity gradient. Fluids for which the viscosity is independent of shear stress are called *Newtonian fluids* and this class includes gases and most common liquids. Polymer solutions, inks, coatings and paints are often non-Newtonian—that is, their thickness and flow characteristics change with shear stress. Viscosity has dimensions of mass per length per time. A common viscosity unit is the poise, defined as one gram per centimeter per second. The kinematic viscosity is defined as the ratio of viscosity to density. A common unit for the kinematic viscosity is the stoke, defined as  $\text{cm}^2/\text{s}$ .

For pure liquids and pure gases at low pressure (near one atm) the viscosity is a function of temperature but is insensitive to changes in pressure. The viscosity of many common gases at low pressure can be found from the nomograph in Perry [1984]; for liquids, constants for 375 compounds appear in Reid *et al.* [1987]. One of the equations used in this tabulation is

$$\ln \eta = A + B/T + CT + DT^2 \quad (194.1)$$

where  $\eta$  is the viscosity in centipoise and  $T$  is the absolute temperature in kelvins. Constants to be used in Eq. (194.1) for liquid water are listed in Table 194.2.

**Table 194.2** Constants for Chapter Equations for Water

Property	Liquid Viscosity	Vapor Thermal Conductivity	Liquid Thermal Conductivity	Ideal Gas Heat Capacity	Vapor Pressure
Eq. in text	(194.1)	(194.2)	(194.3)	(194.5)	(194.9)
$A$	−24.71	$7.341 \cdot 10^{-3}$	−0.03838	32.24	−7.76451
$B$	4209	$−1.013 \cdot 10^{-5}$	$5.254 \cdot 10^{-3}$	0.001924	1.45838
$C$	0.04527	$1.801 \cdot 10^{-7}$	$−6.369 \cdot 10^{-6}$	$1.055 \cdot 10^{-5}$	−2.7758
$D$	$−3.376 \cdot 10^{-5}$	$−9.100 \cdot 10^{-11}$		$−3.596 \cdot 10^{-9}$	−1.23303
$T$ range, K	273–643	273–1070	273–623	273–1500	275–647.3

## 194.2 Thermal Conductivity

The **thermal conductivity** of a fluid is a measure of the rate at which heat is transferred through the fluid by conduction, that is, in the absence of convection. Units used for thermal conductivity

are  $W/(m\ K)$ . These may be converted to English or cgs units by

$$W/(m\ K) \times 0.5778 = \text{Btu}/(\text{h ft } ^\circ\text{R})$$

$$W/(m\ K) \times 0.8604 = \text{kcal}/(\text{cm h K})$$

Yaws and coworkers have used the following equation to correlate the thermal conductivity of 62 different gases:

$$\lambda = A + BT + CT^2 + DT^3 \quad (194.2)$$

and have correlated the thermal conductivity of liquids with the equation:

$$\lambda = A + BT + CT^2 \quad (194.3)$$

In both Eqs. (194.2) and (194.3),  $\lambda$  is the thermal conductivity in  $W/(m\ K)$  and  $T$  is in kelvins. Constants to be used for water vapor in Eq. (194.2) and liquid water in Eq. (194.3) appear in [Table 194.2](#). Constants for the other compounds are listed in both Miller *et al.* [1976] and Reid *et al.* [1987].

## 194.3 Heat Capacity

---

Generally speaking, the **heat capacity** of a fluid is the amount of heat required to increase a unit mass of the substance by one degree. Heat capacities are used to calculate sensible heat effects and are important in the design of heat exchangers. From a historic point of view, the heat capacity of water is of particular significance because, at one time, a calorie was defined as the amount of heat required to heat one gram of water one degree centigrade. The term *specific heat* is the ratio of the heat capacity of a substance to that of water. Although the definition of the calorie is now in terms of joules, and although the heat capacity of water varies slightly with temperature, for engineering purposes the heat capacity of liquid water may still be taken as  $1\ \text{cal}/(\text{g } ^\circ\text{C})$  over the range of 0 to  $100^\circ\text{C}$ . This is particularly convenient because the four sets of units— $\text{cal}/(\text{g } ^\circ\text{C})$ ,  $\text{cal}/(\text{g K})$ ,  $\text{Btu}/(\text{lb } ^\circ\text{F})$ , and  $\text{Btu}/(\text{lb } ^\circ\text{R})$ —are all numerically equivalent. Note that the temperature units in these four sets refer to temperature changes, so  $^\circ\text{C}$  and  $\text{K}$ , for example, are equivalent. Because the heat capacity of water is  $1\ \text{cal}/(\text{g } ^\circ\text{C})$ , the specific heat is numerically equal to the heat capacity when the units are  $\text{cal}/(\text{g } ^\circ\text{C})$ . For gases particularly, heat capacities are often given in molar units. Thus, if a heat capacity with units of  $\text{cal}/(\text{g } ^\circ\text{C})$  is multiplied by a substance's molecular weight, the molar heat capacity in  $\text{cal}/(\text{g mol } ^\circ\text{C})$  is obtained. The units,  $\text{cal}/(\text{g } ^\circ\text{C})$ , may be converted to  $\text{J}/(\text{g } ^\circ\text{C})$  by multiplying by 4.186.

From a rigorous thermodynamic point of view, the term *heat capacity* means heat capacity at constant pressure,  $C_p$ , and is the change in enthalpy with respect to temperature in a constant pressure experiment. However, other heat capacities can be defined. The heat capacity at constant volume,  $C_v$ , is the change in enthalpy with respect to temperature at constant volume, and for

liquids and solids these two heat capacities are essentially the same number. For ideal gases

$$C_p = C_v + R \quad (194.4)$$

Two other heat capacities that are sometimes seen are the change in enthalpy of a saturated liquid with respect to temperature (this path is at neither constant  $P$  nor  $V$  but, rather, along the vapor pressure curve) and the amount of energy required to effect a temperature change while maintaining the liquid in a saturated state. Fortunately, for liquids not close to the critical point and for ideal gases, these latter two heat capacities are essentially the same number as  $C_p$ .

For engineering applications, the heat capacities most often needed are **ideal gas heat capacities** and heat capacities of a condensed phase, that is, liquid or solid. The ideal gas heat capacity,  $C_p^o$ , for a monatomic gas in the ideal gas state, (examples of monatomic compounds include mercury, neon, helium, and argon) is 20.8 J/(g mol K). This is  $2.5R$ , where  $R$  is the gas constant. For compounds that contain more than one atom,  $C_p^o$  is a function of temperature (but not pressure) and its value generally increases with increasing temperature.  $C_p^o$  is correlated with temperature by equations such as

$$C_p^o = A + BT + CT^2 + DT^3 \quad (194.5)$$

and constants for many compounds are tabulated in textbooks, in Reid *et al.* [1987], and in Yaws [1992]. The constants to be used for water in the ideal gas state are listed in Table 194.2.  $T$  is in kelvins and  $C_p^o$  is in J/(g mol K).

The heat capacity of a mixture of ideal gases,  $C_{p,\text{mix}}^o$  may be calculated with the equation

$$C_{p,\text{mix}}^o = \sum_i x_i C_{p,i}^o \quad (194.6)$$

where  $x_i$  is the mole fraction of component  $i$  and  $C_{p,i}^o$  is for pure  $i$ .

For liquids, heat capacities for specific substances can be determined with the nomographs in Perry and Green [1984] or the constants in Yaws [1992]. Liquid heat capacities are weak functions of temperature below the normal boiling point. For some compounds  $C_p$  in this temperature range increases slowly with temperature, but for others  $C_p$  passes through a shallow minimum. The  $C_p$  behavior for water is an example of this latter behavior.  $C_p$  for water passes through a minimum at about 35°C; the values at 0 and 100°C are each about 1% higher than this minimum value. Above the normal boiling point,  $C_p$  for liquids begins to rise and for all compounds approaches infinity as the critical point is approached.

For gases in the nonideal state, and for liquids near the critical point, the heat capacity may be calculated by corresponding states correlations of the type

$$C_p = C_p^o + \Delta C_p^o \quad (194.7)$$

Values of  $\Delta C_p^o$  are functions of both temperature and pressure and may be obtained from tables in Reid *et al.* [1987].

## 194.4 Vapor Pressure

---

The **vapor pressure**, or saturation pressure, of a pure liquid is that pressure where both liquid and vapor are in equilibrium. The vapor pressure is a function only of temperature, and each substance has a unique vapor pressure curve. Three important points on this curve are the normal boiling point, the triple point, and the critical point. The normal boiling point corresponds to that temperature where the vapor pressure is one atm, and the triple point is that one point on the vapor pressure curve where vapor, liquid, and solid can exist in equilibrium. The triple point temperature is essentially the same number as the melting point temperature because pressure has little effect on melting points. At the critical point, the vapor and liquid phases become identical, and, above the critical temperature, the two phases are no longer distinct. The vapor pressure increases rapidly with temperature, and, in fact, the log of the vapor pressure varies nearly linearly with the reciprocal of the absolute temperature. Thus, if vapor pressures are known at two temperatures, reliable vapor pressures can be determined at other temperatures by interpolating on  $\log P_{vp}$  versus  $1/T$ , where  $P_{vp}$  is the vapor pressure and  $T$  is in kelvins. However, this linear relationship is not exact and extrapolations over large temperature ranges can sometimes lead to unacceptable errors.

A number of equations have been developed for correlating vapor pressures. Perhaps the most common is the Antoine equation:

$$\ln P_{vp} = A + \frac{B}{C + T} \quad (194.8)$$

More recently, the Wagner equation has generally been accepted as one of the best equations for correlating vapor pressures. This equation has the form

$$\ln(P_{vp}/P_c) = (A\tau + B\tau^{1.5} + C\tau^3 + D\tau^6)/T_r \quad (194.9)$$

In both Eqs. (194.8) and (194.9), the constants for a particular compound are determined by fitting vapor pressure data. In Eq. (194.9),  $P_c$  is the critical pressure,  $P_{vp}$  is the vapor pressure and will have the same units as  $P_c$ ,  $T_r$  is the reduced temperature,  $T/T_c$ ,  $\tau = 1 - T_r$ , and both  $T$  and  $T_c$  are in kelvins. Some authors have claimed that Eq. (194.9) is improved if the exponents 3 and 6 are replaced with 2.5 and 5. Constants for these equations are listed for 519 compounds in Reid *et al.* [1987]; constants to be used in Eq. (194.9) for water are listed in Table 194.2. Boublík *et al.* [1984] is an excellent source for experimental vapor pressure data. Vapor pressure values can also be found in Perry and Green [1984], Lide [1993], and Shuzo [1976].

### Defining Terms

**Heat capacity:** Generally, constant pressure heat capacity, which is defined as the change in enthalpy with respect to temperature at constant pressure.

**Ideal gas heat capacity:** The heat capacity of a substance at the specified temperature and in the ideal gas state. Unless otherwise stated, this generally means constant pressure heat capacity.

**Thermal conductivity:** The proportionality constant between the heat transfer rate (by conduction) per unit area and the temperature gradient; a measure of how fast heat is transferred by conduction through a substance.

**Vapor pressure:** The pressure at which both the liquid and vapor phases of a pure substance are in equilibrium.

**Viscosity:** The proportionality constant between the shear stress per unit area and the velocity gradient; a measure of the resistance to deformation.

## Further Information

Introductory-level material on heat capacities and vapor pressures can generally be found in thermodynamics textbooks such as *Introduction to Chemical Engineering Thermodynamics* by J. M. Smith and H. C. Van Ness, 4th edition, published by McGraw-Hill in 1987. Introductory-level material on viscosities and thermal conductivities can be found in textbooks dealing with fluid flow and heat transfer, respectively. One such textbook is *Unit Operations of Chemical Engineering*, by W. L. McCabe, J. C. Smith, and P. Harriott, 5th edition, published by McGraw-Hill in 1993. As mentioned in the text, [Table 194.1](#) lists the type of information available in the books listed in the reference section.

### **R. Bruce Martin**

*University of California, Davis*

The term **biomaterials** usually refers to human-made materials used to construct prosthetic or other medical devices for implantation in a human being or materials that otherwise come in contact with the tissues of internal organs (e.g., tubing to carry blood to and from a heart-lung machine). Despite advances in many areas of materials science, it would be a mistake to assume that modern technology has the ability to replace any part of a living organism with an artificial material (or organ) that will be superior to the original structure. Although it is possible to imagine situations in which this might be true in some limited sense, the organism as a whole will rarely work better than when the original organ was in place. For example, a segment of bone may be replaced with a similar structure of titanium alloy having greater strength but lacking the bone's ability to adapt to changing loads and repair fatigue damage over time.

### **195.1 History**

---

The history of biomaterials can be divided into three eras. Prior to 1850 nonmetallic materials, such as wood and ivory, and common metals, such as iron, gold, silver, and copper, were used to fabricate simple prosthetic devices, such as teeth and noses, and to hold fractured bones together while they healed. In 1829 Levert experimented with lead, gold, silver, and platinum wire in dogs, but these metals clearly did not have the desired mechanical attributes. Furthermore, without anesthesia, human patients could not endure long surgeries in order to implant significant prostheses or fixation devices.

The second era of biomaterials was defined by the rapid development of surgery as something other than an emergency procedure, between 1850 and 1925. The advent of anesthesia just prior to the middle of the 19th century precipitated this development. Also, X rays were discovered by

Roentgen and found immediate application in orthopedics in the late 1800s, revealing for the first time the true nature of many skeletal problems. Finally, the acceptance of the aseptic surgical procedures propounded by Lister gradually but dramatically reduced the rate of postsurgical infections.

The period from 1925 to the present is the third era, in which the primary advances in the various surgical specialties have resulted from three important developments. The first was the development of cobalt chrome and stainless steel alloys in the 1930s and 1940s, respectively. The second was the development of polymer chemistry and plastics in the 1940s and 1950s. The third was the discovery of ways to produce useful quantities of penicillin and other antibiotics. The ability to further reduce surgical infection rates and to fabricate many devices that were compatible with biological tissues significantly advanced the ability of surgeons to treat a great variety of problems. Most of the biomaterials commonly in use today were developed more than 25 years ago; the intervening years have been ones of gradual refinement.

## **195.2 Problems Associated with Implanted Devices**

---

There are many problems that a biomaterial should ideally overcome. It must be formable into the desired shape using economical methods and without compromising its mechanical properties. It must not corrode in the presence of body fluids. This property entails the avoidance of crevice and fretting corrosion. A biomaterial must not poison the patient; therefore, it must either be free of toxic substances, or those substances must be adequately locked into the material's structure. A biomaterial must also be easy to sterilize (using steam under pressure, radiation, or ethylene oxide gas) without damaging its properties. The material must not break, either due to an occasional acute overload or due to fatigue from repeated functional loads. The strength and fatigue properties must combine with the shape of the implant to keep stresses within safe limits, particularly where stress concentrations cannot be avoided. Usually, the material must not simply work for a year or two, but for many years. Toxic ions that may be gradually released must not accumulate or lead to a long-term immunological response. A **connective tissue** implant must not perturb the stresses in adjacent tissues into a state that prohibits normal repair of fatigue damage. Finally, implants must be made from materials that can be removed and replaced if they fail. Materials that are impervious to attack by the body may be difficult for the surgeon to remove as well.

### Charnley Total Hip Replacement

*R. B. Martin*

This radiograph is of a Charnley total hip replacement prosthesis implanted in a human patient. The metal femoral component would typically be made from cobalt-chrome alloy and grouted into the femur with polymethylmethacrylate. The latter was Sir John Charnley's innovation, borrowed from dentistry, which made this procedure practical. The hemispherical polyethylene acetabular cup can be seen as the less radiodense material surrounding the top of the femoral component. It has a metal backing which shows as a radio-opaque boundary between the cup and the pelvic bone. The tangle of wire to the left (lateral) side of the prosthesis serves to reattach the greater trochanter to the femur. This ridge of bone is the attachment site for the hip's abductor muscles, which needed to be moved aside to gain access to the joint using the approach standard at that time. It is easier for the body to repair bone than muscle, so it was better to cut the bone than to cut the muscles. Today, other surgical approaches are often used which obviate this problem. (Photo from Waugh, William: *John Charnley: The Man and the Hip*, Springer-Verlag, New York, 1990. With permission.)

## 195.3 Immunology and Biocompatibility

---

All organisms try to keep out foreign matter; if they fail in this, they work very hard either to destroy the invading object if its molecules look destructible or to isolate it by encapsulating it in fibrous tissue if it looks impregnable. The problem of detecting foreign material is very complex, and the problem of defeating an immune system that successfully copes with this task looms very large. Today, people pay surgeons to put foreign objects into them, but their bodies still stick to the old principle of "encapsulate or destroy." In some cases **fibrous encapsulation** does not have an adverse effect on an implant, but, as a general rule, biomaterials should be able to avoid the body's natural inclination to either encapsulate them or break them down. Since doing this by destroying the body's defenses (i.e., the immune system) is a poor tactic, the best way to proceed is to make the implant invisible to the host's chemical sensors. This is difficult to do, since most materials will be easily recognized as "outsiders" and will have a difficult time avoiding the consequences. One useful principle to remember is that materials with molecules that look like biological molecules will be more readily attacked by destructive cells. For example, nylon and polyethylene both have a core of carbon atoms with hydrogens attached along their lengths. The main difference between the two is that polyethylene has a CH<sub>3</sub> terminal group, whereas nylon has an NH<sub>2</sub> terminal group. Since proteins have the latter kind of terminus, nylon tends to be more susceptible than polyethylene to degradation by cells of the immune system.

On the other hand, it may be very difficult to induce the body to attach tissue to impregnable materials such as polyethylene. In fact, no polymers have been found that are both immune to degradation and amenable to tissue adhesion. Some other materials are very attractive to connective tissue cells; for example, hydroxyapatite is nearly identical to bone mineral, and will quickly become integrated with bone when implanted in the skeleton. Unfortunately, hydroxyapatite is not nearly as tough and strong as bone. The commonly used materials that are tough and strong—metals—cannot be destroyed by the immune system, so the body tends to encapsulate them in fibrous tissue. This frustrates attempts to rigidly attach them to bone.

## 195.4 Commonly Used Implant Materials

---

Human-made biomaterials may be broadly categorized into metals, polymers, ceramics, and carbon composites. Each of these categories may contain materials in several forms, such as solids, membranes, fibers, or coatings, and serve many purposes, including replacing structural organs or organs that carry out chemical exchanges, housing electronic devices, repairing damaged or congenitally defective cardiovascular or connective tissue, or delivering drugs.

[Tables 195.1](#) and [195.2](#) show mechanical properties of metals and polymers commonly used as biomaterials. [Table 195.3](#) shows the properties of some connective tissues that these materials are designed to replace.

**Table 195.1** Mechanical Properties of Metals and Ceramics Commonly Used in Biomedical Implants<sup>a</sup>

	Elastic Modulus (GPa)	Maximum Strain (%)	Tensile Strength (MPa)
Stainless steel	193	10	1000
Cast cobalt-Cr	235	8	670
Wrought cobalt-Cr	235	12	1170
Ti-6Al-4V alloy	117	10	900
Pure titanium	100	15	550
Al <sub>2</sub> O <sub>3</sub> <sup>b</sup>	380	0	50
Apatite	62	0	690
C-Si composite	21	0	690

<sup>a</sup>Values in Tables 195.1 through 195.4 are approximations compiled from the references listed at the end of this chapter. Given the variability of biological tissues, and variations in manufacturing processes, precise values cannot be given for mechanical properties.

<sup>b</sup>Compressive strength = 4 GPa.

**Table 195.2** Mechanical Properties of Polymers Commonly Used in Biomedical Implants

Material	Elastic Modulus (MPa)	Maximum Strain (%)	Tensile Strength (MPa)
Silicone rubber <sup>a</sup>	2.4	700	—
Polyether urethane	—	700	41
Bion polymer <sup>a</sup>	1.5	350	13
UHMWPE	500	350	35
PMMA	2000	2	30 <sup>c</sup>
TCF <sup>b</sup>	20000	—	250

<sup>a</sup>Modulus at 100% strain.

<sup>b</sup>Carbon fiber–reinforced traizin resin.

<sup>c</sup>Compressive strength = 90 MPa.

**Table 195.3** Mechanical Properties of Major Connective Tissues

Material	Tensile Strength (MPa)	Elastic Modulus (MPa)	Extensibility (%)
Bone	150	20000	1.5
Cartilage (costal)	1	14	8.0
Collagen (tendon)	75	1300	9.0
Keratin <sup>a</sup>	50	5000	2.0

<sup>a</sup>For the alpha-form region of tensile tests of wool.

## 195.5 Metals

*Cobalt-chromium alloys* were the first corrosion resistant alloys to be developed and have proven very effective in surgical implants, beginning in 1936 when Venable reported the use of such an alloy in orthopedics. They are usually regarded as the metal of choice in skeletal prostheses. They have historically been available in cast and wrought forms; as with stainless steel, the wrought material is substantially stronger. The mechanical properties and compositions of each of the alloys

discussed in this section are shown in [Tables 195.1](#) and [195.4](#), respectively. A modification of Co-Cr alloy contains 35% nickel. It can be forged and heat-treated to obtain tensile strengths significantly above those of stainless steel and Co-Cr alloy—as high as 1800 MPa.

**Table 195.4** Approximate Compositions of Common Biomaterial Alloys

Alloy	Approximate composition
Cobalt-chrome	60% Co, 28% Cr, 6% Mo, 3% Ni, 3% other
Stainless steel	62% Fe, 18% Cr, 14% Ni, 3% Mo, 0.03% C, 3% other
Titanium	90% Ti, 6% Al, 4% V, 0.4% other

*Stainless steel* (usually 316L) is a workhorse industrial alloy that has been very successful as surgical implant material. Both stainless steel and cobalt-chrome alloys owe their corrosion resistance to the formation of a ceramiclike  $\text{CrO}_2$  coating on the surface, and it is important that this coating not be scratched during implantation. The ductility of these alloys can be increased by heat treatment, and their strength can be increased by cold working. Cast stainless steels are unsuitable for orthopedic applications because of their large grain sizes and low fatigue strengths. Type 316LVM (low carbon, vacuum melt) material is preferred.

*Titanium alloys* are primarily Ti-6Al-4V (i.e., 6% aluminum, 4% vanadium, and 90% titanium). (Pure titanium is also used, primarily in dental applications.) This metal is becoming increasingly popular in orthopedics because its strength is as good as the two previous choices, but it is only half as stiff ([Table 195.1](#)). This is potentially important because a large elastic modulus mismatch between implant and bone causes stress concentrations in some places and tends to **stress-shield** the bone in others. However, the modulus of Ti-6Al-4V is still several times greater than bone ([Tables 195.1](#) and [195.3](#)), and marked changes in stress shielding when this alloy is used have not yet been demonstrated.

**Microradiograph of Bone Material**

*R. B. Martin*

Microradiograph of bone (the gray material) which has grown into a porous coralline hydroxyapatite material (white) 16 weeks after implantation into a "window" defect in the radius of a dog. The hydroxyapatite material is used as a bone graft substitute to fill large defects created by trauma or tumor removal. It may be manufactured from coral by a thermochemical process which converts the calcium carbonate manufactured by the marine organism to calcium phosphate. Similar implants may be created by other means; the advantage of using coral is that it has an open porous structure which conveniently accommodates bone ingrowth. While hydroxyapatite is mechanically quite brittle and weak, it is the same mineral normally found in bone and is extremely "osteoconductive"—bone cells readily form new bone on its surfaces with intimate contact between the two materials. Ideally, it would be desirable for the hydroxyapatite to eventually be resorbed and entirely replaced by bone. There are currently insufficient data to know whether or not this will occur. For further information about the materials shown in this microradiograph, see the following:

Martin, R. B., Chapman, M. W., Holmes, R. E., Sartoris, D. J., Shors, E. C., Gordon, J. E., Heitter, D. O., Sharkey, N. A., and Zissimos, A. G. Effects of bone ingrowth on the strength and non-invasive assessment of a coralline hydroxyapatite material. *Biomaterials*. 10:481–488, 1989.

## 195.6 Polymers

*Polymethylmethacrylate* (PMMA) is an acrylic plastic from which parts may be machined. It also may be polymerized in the body to grout a hip prosthesis stem into the medullary canal or fill a bony defect. Frequently, this polymer will have an additive: (1) barium to increase its radiographic

visualization, or (2) an antibiotic to prevent infection following surgery. The mechanical properties of PMMA are shown in [Table 195.2](#); barium and antibiotic additions do not substantially affect these properties. PMMA polymerizes with an exothermic reaction that causes the mass of "dough" used in hip surgery to reach temperatures in the vicinity of 90°C. Also, PMMA has the effect of causing blood pressure to drop momentarily when it is implanted during hip surgery. PMMA is also used in the manufacture of hard contact lenses and of intraocular lenses for cataract patients. For this application, polymerization is initiated with heat to produce an extremely clear material with good optical properties. Soft contact lenses are usually hydrogels made of homo- or copolymers of hydroxyethyl methacrylate; other methacrylates and silicones have also been used, however.

*Ultrahigh-molecular-weight polyethylene* (UHMWPE) has a very simple chemical structure, consisting of chains of carbon atoms with hydrogen atoms attached to the sides. In the ultrahigh-molecular-weight form, these chains achieve a molecular weight of 1 to 4 million. When this material is used as a bearing surface against one of the metal alloys already mentioned, ordinary body fluids are usually sufficient to lubricate the artificial joint and reduce wear problems. Polyethylene has also been used to replace the ossicles of the inner ear.

*Polydimethylsiloxane* (silicone rubber) is a widely used polymer that was first applied biomedically in a hydrocephalus shunt in 1955. It has a long history of biological compatibility and clinical testing in a great variety of applications, and a "medical grade" (Silastic) has been developed with superior **biocompatibility** and mechanical properties. It can be sterilized by steam, radiation, or ethylene oxide. This polymer can be manufactured with various degrees of cross-linking to adapt its mechanical properties for other purposes as well. Silicone rubber is commonly used for catheters. Rubbery sheets of silicone have been used in hernia repair, and a gel silicone has often been used for breast prostheses or augmentation. (The recent controversy over the safety of the latter application is a good example of the difficulty in assessing the biocompatibility of biomaterials. Different individuals may respond quite differently to the same material.) Harder versions have served as balls in ball-and-cage heart valves. Silicone rubber is widely used in pacemakers and biomedical research to form seals against body fluids for electrical leads. It is used as the functional membrane in both kidney dialysis and extracorporeal blood oxygenator machines. It has also been used in drug delivery implants, where it serves as a membrane through which the drug slowly passes. Silicone also serves as a structural material in prosthetic heart valves and to replace the auricle or the ossicles of the ear. In orthopedics, silicone rubber is formed into soft, flexible "strap hinges" for the replacement of arthritic finger, wrist, or toe joints. However, its fatigue resistance is not as good as it should be for this application.

*Dacron* has been used for blood vessel prostheses since the pioneering work of DeBakey in 1951. Dacron is thrombogenic, so the pores in the fabric soon become filled with coagulated blood, which is then replaced by a tissue called *neointima*, which serves as a biological wall between the Dacron and the blood. However, if the vessel diameter is smaller than 6 mm, the neointima will occlude the tube. Dacron has also been used in prosthetic heart valves.

*Polytetrafluoroethylene* (PTFE, Teflon, or Gore-Tex) has been used experimentally to try to produce blood vessel prostheses smaller than 6 mm in diameter, and the neointima appears to be thinner with this material. However, it too is unsatisfactory for most human blood vessels, which are smaller than 3 mm. PTFE is also used to make prosthetic heart valves, ligaments, and artificial

ossicles for the ear.

*Polyether urethane* has been used for years in blood bags and tubing for kidney dialysis machines. It has also been tried as a material for blood vessel replacement. It is frequently found in intraaortic balloon pumps and in artificial hearts, where it lines the chambers and forms the pumping diaphragm. The primary requirement in the latter application is fatigue resistance; a prosthesis that is to last ten years must flex about 360 million times. Materials that have reportedly been tried for this purpose and found wanting include several other polymers used in tubing for kidney dialysis machines: polyvinylchloride, silicone rubber, and natural and synthetic rubbers.

*Polyalkylsulfones* are used in blood oxygenator membranes.

*Hexsyn* and a variation, *Bion*, are brand names of a recently developed elastomer that apparently has good biological compatibility and an extraordinarily high fatigue life (more than 300 million cycles to failure, compared to 600 000 for silicone rubber in an ASTM D430 flexure test). It has been tested in human finger joint prostheses.

*Epoxy resins* have been used to encapsulate electronic implants.

*Polydepsipeptides* and *polylactic acid* polymers have been tested with some success as biodegradable implants. Implant materials that disintegrate gradually in body fluids are useful as sutures and potentially useful as bone plates, to fill defects in bone or other tissues, and for the delivery of embedded drugs.

## 195.7 Ceramics

---

Ceramics generally have hydrophilic surfaces amenable to intimate bonding with tissues. They are very biocompatible but brittle relative to biological materials, including bone. Their primary application may ultimately be as a coating for metals to promote attachment to bone.

*Hydroxyapatite* [ $\text{Ca}_{10}(\text{PO}_4)_6(\text{OH})_2$ ] and *tricalcium phosphate* [TCP,  $\text{Ca}_3(\text{PO}_4)_2$ ] in various forms have proven to be very biocompatible and form intimate bonds with bone. Unfortunately, their tensile strengths are not great. They are primarily viewed as materials that may be made in porous or granular forms and used to fill bone defects in lieu of a bone graft. TCP may eventually be resorbed and replaced by bone; hydroxyapatite is less resorbable.

*Alumina*, a polycrystalline form of  $\text{Al}_2\text{O}_3$ , is a widely used industrial ceramic. It has relatively good strength characteristics but is very stiff and brittle compared to bone. It is sintered from alumina powder under pressure at  $1600^\circ\text{C}$  to form structures with relatively smooth surfaces. A principal use of this material is to form the heads of total hip prostheses (i.e., the ball of the "ball-and-socket" joint).

*Bioglass* ( $\text{Na}_2\text{O}-\text{CaO}-\text{P}_2\text{O}_5-\text{SiO}_2$ ) is a glass with soluble additives designed to form a silica gel at its surface and thereby aid chemical bonding to bone. To date, however, this material has not been widely accepted as an orthopedic biomaterial.

## 195.8 Carbon Materials

---

Carbon is the basis for organic chemistry. Thus, in principle, this element may serve as a good starting point for biocompatible materials. Graphite has a weak, anisotropic crystalline structure,

but isostatic (or turbostratic) carbon is isotropic and relatively strong. The two most useful forms of turbostratic carbon in biomedical applications are vitreous (or glassy) carbon and pyrolytic low-temperature isotropic (LTI) carbon. These are both isotropic materials, but the latter is more wear-resistant and stronger. Turbostratic carbons, carbon-fiber PMMA, and carbon-silicon composites have excellent biocompatibility and can have elastic moduli similar to bone. However, it typically turns out that in order to reduce the stiffness of these materials to that of bone, the strength must be reduced to less than that available in metals. In the last decade a number of these materials have been tested for various biomedical applications, but few have been widely used. Carbon-silicon and carbon-coated graphite have, however, been used to some extent in heart valves, and pyrolytic carbon coating has been shown to improve bone growth into porous metal surfaces.

## Defining Terms

**Biocompatibility:** The ability to remain in direct contact with the tissues of a living person without significantly affecting those tissues, or being affected by them, other than in a prescribed way. For example, a biocompatible material used in a blood vessel wall would contain the blood under pressure but would not adversely interact with its constituents or other adjacent tissues.

**Biomaterial:** An engineering material suitable for use in situations where it may come into direct contact with the internal tissues of the body. Usually, this means in a surgically implanted device, but it may also include devices that contain or process blood or other tissues that will be returned to the body. Sometimes, *biomaterials* is used to refer to biological structural materials.

**Connective tissue:** Tissue that primarily serves a mechanical rather than a metabolic or chemical function. The volume of the cells in such tissue is small relative to the extracellular components. For example, tendons are composed primarily of extracellular collagen, with a small fraction of their volume occupied by the cells that produce the collagen.

**Fibrous encapsulation:** The formation of connective tissues around a foreign object in order to isolate it from the rest of the body, both physically and chemically.

**Stress-shield:** To reduce the stress in a region of bone by placing it in parallel with an implant that is stiffer. Bone is able to adjust its structure to the applied loads, and if the imposed load is reduced, the affected bone will atrophy. This may leave the prosthesis inadequately supported and lead to failure.

This three-dimensional figure represents a single soliton surface for the nonlinear Schrödinger equation  $iq_t + q^2q/2 + q_{xx} = 0$ . The Schrödinger equation arises as a model equation in mathematical physics of atomic behavior. The nonlinear version shown here is one of the next steps in a hierarchy of theories.

This three-dimensional projection was generated using the MAPLE software package. MAPLE is one of three important mathematical computer packages which offer a variety of analytical and numerical software for use by scientists, engineers, and mathematicians. MAPLE was started in 1980 by a group of professors at the University of Waterloo in Canada. The latest version of MAPLE software is well used in the Western world and is strongly supported by the same people at the University of Waterloo.

This figure was developed by W. K. Schief and C. Rogers at the Center for Dynamical Systems and Nonlinear Studies at Georgia Institute of Technology and the University of New South Wales in Sydney, Australia. (Figure courtesy of Schief and Rogers.)

MATHEMATICS HAS BEEN DEFINED AS "the logic of drawing conclusions from arbitrary assumptions." And these conclusions remain valid forevermore! But I hasten to add that mathematics does not supply the assumptions. The engineer does that, but then the conclusions are unambiguous. These mathematical models of the physical world have been remarkably useful. Witness the plethora of equations of all sorts, such as the Navier-Stokes equations, the harmonic oscillator equation, the Korteweg de Vries equation, and so on. All have proven effective in predicting real-world phenomena. But we should not forget that they are not the phenomena, but only *models* of it. Further physical information often leads to improved mathematical models. And that is one of the reasons why a large mathematics section is included in this handbook. A second reason is to provide the reader with a readily available reference for basic and advanced mathematical ideas.

Beginning with a brief review of *analytic geometry* and *calculus*, both differential and integral, the advanced mathematical ideas concentrate on areas that have already been extremely useful. The properties of *vectors* and *matrices* are met first, including operators such as the gradient and curl. *Complex variables* are next in line because of their special nature in the solution of equations, matrix operations, and the solution of certain classes of differential equations.

Increasingly, *difference equations* are being employed to model discrete phenomena as well as in the numerical simulation of the *differential equations*, which are encountered in the following section. Of course, differential equations are the preeminent modeling tools in many fields of engineering. Less familiar are the *integral equations* which arise in certain optimization problems and in the numerical analysis of a variety of equations.

Since many equations are not solvable exactly, a variety of *approximate* (iteration, perturbation, weighted residual) and *numerical methods* have been developed. The latter section is the largest since the developed algorithms are useful on our essential computing machines—the new best friend of the engineer. A brief description of some computer software and packages is appended to this section. Other methods, to help in the solutions of problems, are given in the chapters on *integral transforms* and *optimization*. An important area in optimization is the *calculus of variations*, an old area that grew up with mechanics. *Dimensional analysis* still plays an important role, often offering a quick analysis of a new situation which needs *visualization*.

Of course, no engineer who needs to analyze data could do so without the ideas of *probability and statistics*. Theories of the physical world are continually evolving, so the areas of *chaos*, *fractals*, and *Julia sets* are included as a glimpse into the future. Finally, tables of various kinds are appended to aid the engineer in the search for information.

**Triangles**

In any triangle (in a plane) with sides  $a$ ,  $b$ , and  $c$  and corresponding opposite angles  $A$ ,  $B$ , and  $C$ ,

$$\frac{a}{\sin A} = \frac{b}{\sin B} = \frac{c}{\sin C} \quad (\text{Law of sines})$$

$$a^2 = b^2 + c^2 - 2bc \cos A \quad (\text{Law of cosines})$$

$$\frac{a+b}{a-b} = \frac{\tan \frac{1}{2}(A+B)}{\tan \frac{1}{2}(A-B)} \quad (\text{Law of Tangents})$$

$$\sin \frac{1}{2}A = \sqrt{\frac{(s-b)(s-c)}{bc}} \quad \text{where } s = \frac{1}{2}(a+b+c)$$

$$\cos \frac{1}{2}A = \sqrt{\frac{s(s-a)}{bc}}$$

$$\tan \frac{1}{2}A = \sqrt{\frac{(s-b)(s-c)}{s(s-a)}}$$

$$\begin{aligned}\text{Area} &= \frac{1}{2}bc \sin A \\ &= \sqrt{s(s-a)(s-b)(s-c)}\end{aligned}$$

If the vertices have coordinates  $(x_1, y_1)$ ,  $(x_2, y_2)$ ,  $(x_3, y_3)$ , the area is the *absolute value* of the expression

$$\frac{1}{2} \begin{vmatrix} x_1 & y_1 & 1 \\ x_2 & y_2 & 1 \\ x_3 & y_3 & 1 \end{vmatrix}$$

## Trigonometric Functions of an Angle

With reference to [Fig. 196.1](#),  $P(x, y)$  is a point in any one of the four quadrants and  $A$  is an angle whose initial side is coincident with the positive  $x$  axis and whose terminal side contains the point  $P(x, y)$ . The distance from the origin  $P(x, y)$  is denoted by  $r$  and is positive. The trigonometric functions of the angle  $A$  are defined as:

$$\begin{aligned}\sin A &= \text{sine } A &&= y/r \\ \cos A &= \text{cosine } A &&= x/r \\ \tan A &= \text{tangent } A &&= y/x \\ \text{ctn } A &= \text{cotangent } A &&= x/y \\ \sec A &= \text{secant } A &&= r/x \\ \csc A &= \text{cosecant } A &&= r/y\end{aligned}$$

Angles are measured in degrees or radians;  $180^\circ = \pi$  radians; 1 radian =  $180/\pi$  degrees. The trigonometric functions of  $0^\circ$ ,  $30^\circ$ ,  $45^\circ$ , and integer multiples of these are directly computed.

	$0^\circ$	$30^\circ$	$45^\circ$	$60^\circ$	$90^\circ$	$120^\circ$	$135^\circ$	$150^\circ$	$180^\circ$
sin	0	$\frac{1}{2}$	$\frac{\sqrt{2}}{2}$	$\frac{\sqrt{3}}{2}$	1	$\frac{\sqrt{3}}{2}$	$\frac{\sqrt{2}}{2}$	$\frac{1}{2}$	0
cos	1	$\frac{\sqrt{3}}{2}$	$\frac{\sqrt{2}}{2}$	$\frac{1}{2}$	0	$-\frac{1}{2}$	$-\frac{\sqrt{2}}{2}$	$-\frac{\sqrt{3}}{2}$	-1
tan	0	$\frac{\sqrt{3}}{3}$	1	$\sqrt{3}$	$\infty$	$-\sqrt{3}$	-1	$-\frac{\sqrt{3}}{3}$	0

ctn	$\infty$	$\sqrt{3}$	1	$\frac{\sqrt{3}}{3}$	0	$-\frac{\sqrt{3}}{3}$	-1	$-\sqrt{3}$	$\infty$
sec	1	$\frac{2\sqrt{3}}{3}$	$\sqrt{2}$	2	$\infty$	-2	$-\sqrt{2}$	$\frac{2\sqrt{3}}{3}$	-1
csc	$\infty$	$\frac{3}{2}$	$\sqrt{2}$	$\frac{2\sqrt{3}}{3}$	1	$\frac{2\sqrt{3}}{3}$	$\sqrt{2}$	$\frac{3}{2}$	$\infty$

**Figure 196.1** The trigonometric point. Angle  $A$  is taken to be positive when the rotation is counterclockwise and negative when the rotation is clockwise. The plane is divided into quadrants as shown.

## Trigonometric Identities

$$\sin A = \frac{1}{\csc A}$$

$$\cos A = \frac{1}{\sec A}$$

$$\tan A = \frac{1}{\cot A} = \frac{\sin A}{\cos A}$$

$$\csc A = \frac{1}{\sin A}$$

$$\sec A = \frac{1}{\cos A}$$

$$\cot A = \frac{1}{\tan A} = \frac{\cos A}{\sin A}$$

$$\sin^2 A + \cos^2 A = 1$$

$$1 + \tan^2 A = \sec^2 A$$

$$1 + \cot^2 A = \csc^2 A$$

$$\sin(A \pm B) = \sin A \cos B \pm \cos A \sin B$$

$$\cos(A \pm B) = \cos A \cos B \mp \sin A \sin B$$

$$\tan(A \pm B) = \frac{\tan A \pm \tan B}{1 \mp \tan A \tan B}$$

$$\sin 2A = 2 \sin A \cos A$$

$$\sin 3A = 3 \sin A - 4 \sin^3 A$$

$$\sin nA = 2 \sin(n-1)A \cos A - \sin(n-2)A$$

$$\cos 2A = 2 \cos^2 A - 1 = 1 - 2 \sin^2 A$$

$$\cos 3A = 4 \cos^3 A - 3 \cos A$$

$$\cos nA = 2 \cos(n-1)A \cos A - \cos(n-2)A$$

$$\begin{aligned}\sin A + \sin B &= 2 \sin \frac{1}{2}(A+B) \cos \frac{1}{2}(A-B) \\ \sin A - \sin B &= 2 \cos \frac{1}{2}(A+B) \sin \frac{1}{2}(A-B) \\ \cos A + \cos B &= 2 \cos \frac{1}{2}(A+B) \cos \frac{1}{2}(A-B) \\ \cos A - \cos B &= -2 \sin \frac{1}{2}(A+B) \sin \frac{1}{2}(A-B)\end{aligned}$$

$$\begin{aligned}\tan A \pm \tan B &= \frac{\sin(A \pm B)}{\cos A \cos B} \\ \operatorname{ctn} A \pm \operatorname{ctn} B &= \pm \frac{\sin(A \pm B)}{\sin A \sin B}\end{aligned}$$

$$\begin{aligned}\sin A \sin B &= \frac{1}{2} \cos(A-B) - \frac{1}{2} \cos(A+B) \\ \cos A \cos B &= \frac{1}{2} \cos(A-B) + \frac{1}{2} \cos(A+B) \\ \sin A \cos B &= \frac{1}{2} \sin(A+B) + \frac{1}{2} \sin(A-B)\end{aligned}$$

$$\begin{aligned}\sin \frac{A}{2} &= \pm \sqrt{\frac{1 - \cos A}{2}} \\ \cos \frac{A}{2} &= \pm \sqrt{\frac{1 + \cos A}{2}} \\ \tan \frac{A}{2} &= \frac{1 - \cos A}{\sin A} = \frac{\sin A}{1 + \cos A} = \pm \sqrt{\frac{1 - \cos A}{1 + \cos A}}\end{aligned}$$

$$\begin{aligned}\sin^2 A &= \frac{1}{2}(1 - \cos 2A) \\ \cos^2 A &= \frac{1}{2}(1 + \cos 2A) \\ \sin^3 A &= \frac{1}{4}(3 \sin A - \sin 3A) \\ \cos^3 A &= \frac{1}{4}(\cos 3A + 3 \cos A)\end{aligned}$$

$$\sin ix = \frac{1}{2}i(e^x - e^{-x}) = i \sinh x$$

$$\cos ix = \frac{1}{2}(e^x + e^{-x}) = \cosh x$$

$$\tan ix = \frac{i(e^x - e^{-x})}{e^x + e^{-x}} = i \tanh x$$

$$e^{x+iy} = e^x(\cos y + i \sin y)$$

$$(\cos x \pm i \sin x)^n = \cos nx \pm i \sin nx$$

## Inverse Trigonometric Functions

The inverse trigonometric functions are multiple valued, and this should be taken into account in the use of the following formulas.

$$\begin{aligned}\sin^{-1} x &= \cos^{-1} \sqrt{1-x^2} \\ &= \tan^{-1} \frac{x}{\sqrt{1-x^2}} = \operatorname{ctn}^{-1} \frac{\sqrt{1-x^2}}{x} \\ &= \sec^{-1} \frac{1}{\sqrt{1-x^2}} = \operatorname{csc}^{-1} \frac{1}{x} \\ &= -\sin^{-1}(-x)\end{aligned}$$

$$\begin{aligned}\cos^{-1} x &= \sin^{-1} \sqrt{1-x^2} \\ &= \tan^{-1} \frac{\sqrt{1-x^2}}{x} = \operatorname{ctn}^{-1} \frac{x}{\sqrt{1-x^2}} \\ &= \sec^{-1} \frac{1}{x} = \operatorname{csc}^{-1} \frac{1}{\sqrt{1-x^2}} \\ &= \pi - \cos^{-1}(-x)\end{aligned}$$

$$\begin{aligned}\tan^{-1} x &= \operatorname{ctn}^{-1} \frac{1}{x} \\ &= \sin^{-1} \frac{x}{\sqrt{1+x^2}} = \cos^{-1} \frac{1}{\sqrt{1+x^2}} \\ &= \sec^{-1} \sqrt{1+x^2} = \operatorname{csc}^{-1} \frac{\sqrt{1+x^2}}{x}\end{aligned}$$

## 196.2 Series

---

### Bernoulli and Euler Numbers

A set of numbers,  $B_1, B_3, \dots, B_{2n-1}$  (Bernoulli numbers) and  $B_2, B_4, \dots, B_{2n}$  (Euler numbers) appear in the series expansions of many functions. A partial listing follows; these are computed from the following equations:

$$B_{2n} - \frac{2n(2n-1)}{2!} B_{2n-2} + \frac{2n(2n-1)(2n-2)(2n-3)}{4!} B_{2n-4} - \dots + (-1)^n = 0$$

and

$$\begin{aligned} \frac{2^{2n}(2^{2n}-1)}{2n} B_{2n-1} &= (2n-1) B_{2n-2} \\ &\quad - \frac{(2n-1)(2n-2)(2n-3)}{3!} B_{2n-4} + \dots + (-1)^{n-1} \end{aligned}$$

$$B_1 = 1/6 \qquad B_2 = 1$$

$$B_3 = 1/30 \qquad B_4 = 5$$

$$B_5 = 1/42 \qquad B_6 = 61$$

$$B_7 = 1/30 \qquad B_8 = 1385$$

$$B_9 = 5/66 \qquad B_{10} = 50\,521$$

$$B_{11} = 691/2730 \qquad B_{12} = 2\,702\,765$$

$$B_{13} = 7/6 \qquad B_{14} = 199\,360\,981$$

$$\vdots$$

$$\vdots$$

### Series of Functions

In the following, the interval of convergence is indicated; otherwise it is all  $x$ . Logarithms are to the base  $e$ . Bernoulli and Euler numbers ( $B_{2n-1}$  and  $B_{2n}$ ) appear in certain expressions.

$$\begin{aligned}
(a+x)^n &= a^n + na^{n-1}x \\
&+ \frac{n(n-1)}{2!}a^{n-2}x^2 + \frac{n(n-1)(n-2)}{3!}a^{n-3}x^3 + \dots \\
&+ \frac{n!}{(n-j)!j!}a^{n-j}x^j + \dots
\end{aligned}
\quad [x^2 < a^2]$$

$$(a-bx)^{-1} = \frac{1}{a} \left[ 1 + \frac{bx}{a} + \frac{b^2x^2}{a^2} + \frac{b^3x^3}{a^3} + \dots \right] \quad [b^2x^2 < a^2]$$

$$(1 \pm x)^n = 1 \pm nx + \frac{n(n-1)}{2!}x^2 \pm \frac{n(n-1)(n-2)x^3}{3!} + \dots \quad [x^2 < 1]$$

$$(1 \pm x)^{-n} = 1 \mp nx + \frac{n(n+1)}{2!}x^2 \mp \frac{n(n+1)(n+2)}{3!}x^3 + \dots \quad [x^2 < 1]$$

$$(1 \pm x)^{1/2} = 1 \pm \frac{1}{2}x - \frac{1}{2 \cdot 4}x^2 \pm \frac{1 \cdot 3}{2 \cdot 4 \cdot 6}x^3 - \frac{1 \cdot 3 \cdot 5}{2 \cdot 4 \cdot 6 \cdot 8}x^4 \pm \dots \quad [x^2 < 1]$$

$$(1 \pm x)^{-1/2} = 1 \mp \frac{1}{2}x + \frac{1 \cdot 3}{2 \cdot 4}x^2 \mp \frac{1 \cdot 3 \cdot 5}{2 \cdot 4 \cdot 6}x^3 + \frac{1 \cdot 3 \cdot 5 \cdot 7}{2 \cdot 4 \cdot 6 \cdot 8}x^4 \pm \dots \quad [x^2 < 1]$$

$$(1 \pm x^2)^{1/2} = 1 \pm \frac{1}{2}x^2 - \frac{x^4}{2 \cdot 4} \pm \frac{1 \cdot 3}{2 \cdot 4 \cdot 6}x^6 - \frac{1 \cdot 3 \cdot 5}{2 \cdot 4 \cdot 6 \cdot 8}x^8 \pm \dots \quad [x^2 < 1]$$

$$(1 \pm x)^{-1} = 1 \mp x + x^2 \mp x^3 + x^4 \mp x^5 + \dots \quad [x^2 < 1]$$

$$(1 \pm x)^{-2} = 1 \mp 2x + 3x^2 \mp 4x^3 + 5x^4 \mp \dots \quad [x^2 < 1]$$

$$e^x = 1 + x + \frac{x^2}{2!} + \frac{x^3}{3!} + \frac{x^4}{4!} + \dots$$

$$e^{-x^2} = 1 - x^2 + \frac{x^4}{2!} - \frac{x^6}{3!} + \frac{x^8}{4!} - \dots$$

$$a^x = 1 + x \log a + \frac{(x \log a)^2}{2!} + \frac{(x \log a)^3}{3!} + \dots$$

$$\log x = (x-1) - \frac{1}{2}(x-1)^2 + \frac{1}{3}(x-1)^3 - \dots \quad [0 < x < 2]$$

$$\log x = \frac{x-1}{x} + \frac{1}{2} \left( \frac{x-1}{x} \right)^2 + \frac{1}{3} \left( \frac{x-1}{x} \right)^3 + \dots \quad \left[ x > \frac{1}{2} \right]$$

$$\begin{aligned}\log x &= 2 \left[ \left( \frac{x-1}{x+1} \right) + \frac{1}{3} \left( \frac{x-1}{x+1} \right)^3 + \frac{1}{5} \left( \frac{x-1}{x+1} \right)^5 + \cdots \right] & [x > 0] \\ \log(1+x) &= x - \frac{1}{2}x^2 + \frac{1}{3}x^3 - \frac{1}{4}x^4 + \cdots & [x^2 < 1] \\ \log \left( \frac{1+x}{1-x} \right) &= 2 \left[ x + \frac{1}{3}x^3 + \frac{1}{5}x^5 + \frac{1}{7}x^7 + \cdots \right] & [x^2 < 1] \\ \log \left( \frac{x+1}{x-1} \right) &= 2 \left[ \frac{1}{x} + \frac{1}{3} \left( \frac{1}{x} \right)^3 + \frac{1}{5} \left( \frac{1}{x} \right)^5 + \cdots \right] & [x^2 > 1] \\ \sin x &= x - \frac{x^3}{3!} + \frac{x^5}{5!} - \frac{x^7}{7!} + \cdots \\ \cos x &= 1 - \frac{x^2}{2!} + \frac{x^4}{4!} - \frac{x^6}{6!} + \cdots \\ \tan x &= x + \frac{x^3}{3} + \frac{2x^5}{15} + \frac{17x^7}{315} \\ &\quad + \cdots + \frac{2^{2n}(2^{2n}-1)B_{2n-1}x^{2n-1}}{(2n)!} & \left[ x^2 < \frac{\pi^2}{4} \right] \\ \operatorname{ctn} x &= \frac{1}{x} - \frac{x}{3} - \frac{x^3}{45} - \frac{2x^5}{945} - \cdots - \frac{B_{2n-1}(2x)^{2n}}{(2n)!x} - \cdots & [x^2 < \pi^2] \\ \sec x &= 1 + \frac{x^2}{2!} + \frac{5x^4}{4!} + \frac{61x^6}{6!} + \cdots + \frac{B_{2n}x^{2n}}{(2n)!} + \cdots & \left[ x^2 < \frac{\pi^2}{4} \right] \\ \csc x &= \frac{1}{x} + \frac{x}{3!} + \frac{7x^3}{3 \cdot 5!} + \frac{31x^5}{3 \cdot 7!} + \cdots \\ &\quad + \frac{2(2^{2n+1}-1)}{(2n+2)!} B_{2n+1} x^{2n+1} + \cdots & [x^2 < \pi^2] \\ \sin^{-1} x &= x + \frac{x^3}{6} + \frac{(1 \cdot 3)x^5}{(2 \cdot 4)5} + \frac{(1 \cdot 3 \cdot 5)x^7}{(2 \cdot 4 \cdot 6)7} + \cdots & [x^2 < 1] \\ \tan^{-1} x &= x - \frac{1}{3}x^3 + \frac{1}{5}x^5 - \frac{1}{7}x^7 + \cdots & [x^2 < 1] \\ \sec^{-1} x &= \frac{\pi}{2} - \frac{1}{x} - \frac{1}{6x^3} - \frac{1 \cdot 3}{(2 \cdot 4)5x^5} - \frac{1 \cdot 3 \cdot 5}{(2 \cdot 4 \cdot 6)7x^7} - \cdots & [x^2 > 1] \\ \sinh x &= x + \frac{x^3}{3!} + \frac{x^5}{5!} + \frac{x^7}{7!} + \cdots \\ \cosh x &= 1 + \frac{x^2}{2!} + \frac{x^4}{4!} + \frac{x^6}{6!} + \frac{x^8}{8!} + \cdots\end{aligned}$$

$$\begin{aligned}\tanh x &= (2^2 - 1)2^2 B_1 \frac{x}{2!} - (2^4 - 1)2^4 B_3 \frac{x^3}{4!} \\ &\quad + (2^6 - 1)2^6 B_5 \frac{x^5}{6!} - \dots\end{aligned}\quad \left[ x^2 < \frac{\pi^2}{4} \right]$$

$$\operatorname{ctnh} x = \frac{1}{x} \left( 1 + \frac{2^2 B_1 x^2}{2!} - \frac{2^4 B_3 x^4}{4!} + \frac{2^6 B_5 x^6}{6!} - \dots \right) \quad [x^2 < \pi^2]$$

$$\operatorname{sech} x = 1 - \frac{B_2 x^2}{2!} + \frac{B_4 x^4}{4!} - \frac{B_6 x^6}{6!} + \dots \quad \left[ x^2 < \frac{\pi^2}{4} \right]$$

$$\operatorname{csch} x = \frac{1}{x} - (2 - 1)2B_1 \frac{x}{2!} + (2^3 - 1)2B_3 \frac{x^3}{4!} - \dots \quad [x^2 < \pi^2]$$

$$\sinh^{-1} x = x - \frac{1}{2} \frac{x^3}{3} + \frac{1 \cdot 3}{2 \cdot 4} \frac{x^5}{5} - \frac{1 \cdot 3 \cdot 5}{2 \cdot 4 \cdot 6} \frac{x^7}{7} + \dots \quad [x^2 < 1]$$

$$\tanh^{-1} x = x + \frac{x^3}{3} + \frac{x^5}{5} + \frac{x^7}{7} + \dots \quad [x^2 < 1]$$

$$\operatorname{ctnh}^{-1} x = \frac{1}{x} + \frac{1}{3x^3} + \frac{1}{5x^5} + \dots \quad [x^2 > 1]$$

$$\operatorname{csch}^{-1} x = \frac{1}{x} - \frac{1}{2 \cdot 3x^3} + \frac{1 \cdot 3}{2 \cdot 4 \cdot 5x^5} - \frac{1 \cdot 3 \cdot 5}{2 \cdot 4 \cdot 6 \cdot 7x^7} + \dots \quad [x^2 > 1]$$

$$\int_0^x e^{-t^2} dt = x - \frac{1}{3}x^3 + \frac{x^5}{5 \cdot 2!} - \frac{x^7}{7 \cdot 3!} + \dots$$

## Error Function

The following function, known as the error function,  $\operatorname{erf} x$ , arises frequently in applications:

$$\operatorname{erf} x = \frac{2}{\sqrt{\pi}} \int_0^x e^{-t^2} dt$$

The integral cannot be represented in terms of a finite number of elementary functions; therefore, values of  $\operatorname{erf} x$  have been compiled in tables. The following is the series for  $\operatorname{erf} x$ :

$$\operatorname{erf} x = \frac{2}{\sqrt{\pi}} \left[ x - \frac{x^3}{3} + \frac{x^5}{5 \cdot 2!} - \frac{x^7}{7 \cdot 3!} + \dots \right]$$

There is a close relation between this function and the area under the standard normal curve. For evaluation it is convenient to use  $z$  instead of  $x$ ; then  $\operatorname{erf} z$  may be evaluated from the area  $F(z)$  by use of the relation

$$\operatorname{erf} z = 2F(\sqrt{2}z)$$

### Example

$$\operatorname{erf}(0.5) = 2F[(1.414)(0.5)] = 2F(0.707)$$

By interpolation,  $F(0.707) = 0.260$ ; thus,  $\operatorname{erf}(0.5) = 0.520$ .

## Series Expansion

The expression in parentheses following certain series indicates the region of convergence. If not otherwise indicated, it is understood that the series converges for all finite values of  $x$ .

### Binomial

$$\begin{aligned} (x + y)^n &= x^n + nx^{n-1}y + \frac{n(n-1)}{2!}x^{n-2}y^2 \\ &\quad + \frac{n(n-1)(n-2)}{3!}x^{n-3}y^3 + \cdots \end{aligned} \quad (y^2 < x^2)$$

$$(1 \pm x)^n = 1 \pm nx + \frac{n(n-1)x^2}{2!} \pm \frac{n(n-1)(n-2)x^3}{3!} + \cdots \quad (x^2 < 1)$$

$$(1 \pm x)^{-n} = 1 \mp nx + \frac{n(n+1)x^2}{2!} \mp \frac{n(n+1)(n+2)x^3}{3!} + \cdots \quad (x^2 < 1)$$

$$(1 \pm x)^{-1} = 1 \mp x + x^2 \mp x^3 + x^4 \mp x^5 + \cdots \quad (x^2 < 1)$$

$$(1 \pm x)^{-2} = 1 \mp 2x + 3x^2 \mp 4x^3 + 5x^4 \mp 6x^5 + \cdots \quad (x^2 < 1)$$

### Reversion of Series

Let a series be represented by

$$y = a_1x + a_2x^2 + a_3x^3 + a_4x^4 + a_5x^5 + a_6x^6 + \cdots \quad (a_1 \neq 0)$$

To find the coefficients of the series

$$x = A_1 y + A_2 y^2 + A_3 y^3 + A_4 y^4 + \dots$$

$$A_1 = \frac{1}{a_1} \quad A_2 = -\frac{a_2}{a_1^3} \quad A_3 = \frac{1}{a_1^5} (2a_2^2 - a_1 a_3)$$

$$A_4 = \frac{1}{a_1^7} (5a_1 a_2 a_3 - a_1^2 a_4 - 5a_2^3)$$

$$A_5 = \frac{1}{a_1^9} (6a_1^2 a_2 a_4 + 3a_1^2 a_3^2 + 14a_2^4 - a_1^3 a_5 - 21a_1 a_2^2 a_3)$$

$$A_6 = \frac{1}{a_1^{11}} (7a_1^3 a_2 a_5 + 7a_1^3 a_3 a_4 + 84a_1 a_2^3 a_3 - a_1^4 a_6 \\ - 28a_1^2 a_2^2 a_4 - 28a_1^2 a_2 a_3^2 - 42a_2^5)$$

$$A_7 = \frac{1}{a_1^{13}} (8a_1^4 a_2 a_6 + 8a_1^4 a_3 a_5 + 4a_1^4 a_4^2 + 120a_1^2 a_2^3 a_4 \\ + 180a_1^2 a_2^2 a_3^2 + 132a_2^6 - a_1^5 a_7 \\ - 36a_1^3 a_2^2 a_5 - 72a_1^3 a_2 a_3 a_4 \\ - 12a_1^3 a_3^3 - 330a_1 a_2^4 a_3)$$

## Taylor

1.

$$f(x) = f(a) + (x-a)f'(a) + \frac{(x-a)^2}{2!}f''(a) + \frac{(x-a)^3}{3!}f'''(a) \\ + \dots + \frac{(x-a)^n}{n!}f^{(n)}(a) + \dots \quad (\text{Taylor's series})$$

(Increment Form)

2.

$$f(x+h) = f(x) + hf'(x) + \frac{h^2}{2!}f''(x) + \frac{h^3}{3!}f'''(x) + \dots \\ = f(h) + xf'(h) + \frac{x^2}{2!}f''(h) + \frac{x^3}{3!}f'''(h) + \dots$$

3. If  $f(x)$  is a function possessing derivatives of all orders throughout the interval  $a \leq X \leq b$ , then there is a value  $X$ , with  $a < X < b$ , such that

$$\begin{aligned}
f(b) &= f(a) + (b-a)f'(a) + \frac{(b-a)^2}{2!}f''(a) + \cdots \\
&\quad + \frac{(b-a)^{n-1}}{(n-1)!}f^{(n-1)}(a) + \frac{(b-a)^n}{n!}f^{(n)}(a) \\
f(a+h) &= f(a) + hf'(a) + \frac{h^2}{2!}f''(a) + \cdots + \frac{h^{n-1}}{(n-1)!}f^{(n-1)}(a) \\
&\quad + \frac{h^n}{n!}f^{(n)}(a+\theta h), \quad b = a+h, \quad 0 < \theta < 1
\end{aligned}$$

or

$$f(x) = f(a) + (x-a)f'(a) + \frac{(x-a)^2}{2!}f''(a) + \cdots + (x-a)^{n-1}\frac{f^{(n-1)}(a)}{(n-1)!} + R_n$$

where

$$R_n = \frac{f^{(n)}[a+\theta(x-a)]}{n!}(x-a)^n, \quad 0 < \theta < 1.$$

The above forms are known as Taylor's series with the remainder term.

4. Taylor's series for a function of two variables:

$$\begin{aligned}
\text{If } \left(h\frac{\partial}{\partial x} + k\frac{\partial}{\partial y}\right) f(x,y) &= h\frac{\partial f(x,y)}{\partial x} + k\frac{\partial f(x,y)}{\partial y}; \\
\left(h\frac{\partial}{\partial x} + k\frac{\partial}{\partial y}\right)^2 f(x,y) &= h^2\frac{\partial^2 f(x,y)}{\partial x^2} + 2hk\frac{\partial^2 f(x,y)}{\partial x\partial y} + k^2\frac{\partial^2 f(x,y)}{\partial y^2}
\end{aligned}$$

etc., and if

$$\left(h\frac{\partial}{\partial x} + k\frac{\partial}{\partial y}\right)^n f(x,y) \Big|_{\substack{x=a \\ y=b}}$$

where the bar and subscripts mean that after differentiation we are to replace  $x$  by  $a$  and  $y$  by  $b$ ,

$$\begin{aligned}
f(a+h, b+k) &= f(a,b) + \left(h\frac{\partial}{\partial x} + k\frac{\partial}{\partial y}\right) f(x,y) \Big|_{\substack{x=a \\ y=b}} + \cdots \\
&\quad + \frac{1}{n!} \left(h\frac{\partial}{\partial x} + k\frac{\partial}{\partial y}\right)^n f(x,y) \Big|_{\substack{x=a \\ y=b}} + \cdots
\end{aligned}$$

## MacLaurin

$$f(x) = f(0) + xf'(0) + \frac{x^2}{2!}f''(0) + \frac{x^3}{3!}f'''(0) + \cdots + x^{n-1}\frac{f^{(n-1)}(0)}{(n-1)!} + R_n$$

where

$$R_n = \frac{x^n f^{(n)}(\theta x)}{n!}, \quad 0 < \theta < 1$$

## Exponential

$$e = 1 + \frac{1}{1!} + \frac{1}{2!} + \frac{1}{3!} + \frac{1}{4!} + \cdots$$

$$e^x = 1 + x + \frac{x^2}{2!} + \frac{x^3}{3!} + \frac{x^4}{4!} + \cdots \quad (\text{all real values of } x)$$

$$a^x = 1 + x \log_e a + \frac{(x \log_e a)^2}{2!} + \frac{(x \log_e a)^3}{3!} + \cdots$$

$$e^x = e^a \left[ 1 + (x - a) + \frac{(x - a)^2}{2!} + \frac{(x - a)^3}{3!} + \cdots \right]$$

## Logarithmic

$$\log_e x = \frac{x-1}{x} + \frac{1}{2} \left( \frac{x-1}{x} \right)^2 + \frac{1}{3} \left( \frac{x-1}{x} \right)^3 + \dots \quad (x > \tfrac{1}{2})$$

$$\log_e x = (x-1) - \tfrac{1}{2}(x-1)^2 + \tfrac{1}{3}(x-1)^3 - \dots \quad (2 \geq x > 0)$$

$$\log_e x = 2 \left[ \frac{x-1}{x+1} + \frac{1}{3} \left( \frac{x-1}{x+1} \right)^3 - \frac{1}{5} \left( \frac{x-1}{x+1} \right)^5 + \dots \right] \quad (x > 0)$$

$$\log_e(1+x) = x - \tfrac{1}{2}x^2 + \tfrac{1}{3}x^3 - \tfrac{1}{4}x^4 + \dots \quad (-1 < x \leq 1)$$

$$\log_e(n+1) - \log_e(n-1) = 2 \left[ \frac{1}{n} + \frac{1}{3n^3} + \frac{1}{5n^5} + \dots \right]$$

$$\log_e(a+x) = \log_e a + 2 \left[ \frac{x}{2a+x} + \frac{1}{3} \left( \frac{x}{2a+x} \right)^3 + \frac{1}{5} \left( \frac{x}{2a+x} \right)^5 + \dots \right] \\ (a > 0, -a < x < +\infty)$$

$$\log_e \frac{1+x}{1-x} = 2 \left[ x + \frac{x^3}{3} + \frac{x^5}{5} + \dots + \frac{x^{2n-1}}{2n-1} + \dots \right] \quad (-1 < x < 1)$$

$$\log_e x = \log_e a + \frac{(x-a)}{a} - \frac{(x-a)^2}{2a^2} + \frac{(x-a)^3}{3a^3} - \dots \\ (0 < x \leq 2a)$$

## Trigonometric

$$\sin x = x - \frac{x^3}{3!} + \frac{x^5}{5!} - \frac{x^7}{7!} + \dots \quad (\text{all real values of } x)$$

$$\cos x = 1 - \frac{x^2}{2!} + \frac{x^4}{4!} - \frac{x^6}{6!} + \dots \quad (\text{all real values of } x)$$

$$\tan x = x + \frac{x^3}{3} + \frac{2x^5}{15} + \frac{17x^7}{315} + \frac{62x^9}{2835} + \dots$$

$$+ \frac{(-1)^{n-1} 2^{2n} (2^{2n} - 1) B_{2n}}{(2n)!} x^{2n-1} + \dots$$

( $x^2 < \pi^2/4$ , and  $B_n$  represents the  $n$ th Bernoulli number )

$$\cot x = \frac{1}{x} - \frac{x}{3} - \frac{x^2}{45} - \frac{2x^5}{945} - \frac{x^7}{4725} - \dots$$

$$- \frac{(-1)^{n+1} 2^{2n}}{(2n)!} B_{2n} x^{2n-1} + \dots$$

( $x^2 < \pi^2$ , and  $B_n$  represents the  $n$ th Bernoulli number )

## 196.3 Differential Calculus

---

### Notation

For the following equations, the symbols  $f(x)$ ,  $g(x)$ , etc., represent functions of  $x$ . The value of a function  $f(x)$  at  $x = a$  is denoted  $f(a)$ . For the function  $y = f(x)$  the derivative of  $y$  with respect to  $x$  is denoted by one of the following:

$$\frac{dy}{dx}, \quad f'(x), \quad D_x y, \quad y'$$

Higher derivatives are as follows:

$$\frac{d^2 y}{dx^2} = \frac{d}{dx} \left( \frac{dy}{dx} \right) = \frac{d}{dx} f'(x) = f''(x)$$

$$\frac{d^3 y}{dx^3} = \frac{d}{dx} \left( \frac{d^2 y}{dx^2} \right) = \frac{d}{dx} f''(x) = f'''(x)$$

$\vdots$

and values of these at  $x = a$  are denoted  $f'(a)$ ,  $f'''(a)$ , and so on (see Table of Derivatives in Appendix).

### Slope of a Curve

The tangent line at point  $P(x,y)$  of the curve  $y = f(x)$  has a slope  $f'(x)$  provided that  $f'(x)$  exists at  $P$ .

The slope at  $P$  is defined to be that of the tangent line at  $P$ . The tangent line at  $P(x_1, y_1)$  is given by

$$y - y_1 = f'(x_1)(x - x_1)$$

The *normal line* to the curve at  $P(x_1, y_1)$  has slope  $-1/f'(x_1)$  and thus obeys the equation

$$y - y_1 = [-1/f'(x_1)](x - x_1)$$

(The slope of a vertical line is not defined.)

## Angle of Intersection of Two Curves

Two curves,  $y = f_1(x)$  and  $y = f_2(x)$ , that intersect at a point  $P(X, Y)$  where derivatives  $f'_1(X), f'_2(X)$  exist, have an angle ( $\alpha$ ) of intersection given by

$$\tan \alpha = \frac{f'_2(X) - f'_1(X)}{1 + f'_2(X) \cdot f'_1(X)}$$

If  $\tan \alpha > 0$ , then  $\alpha$  is the acute angle; if  $\tan \alpha < 0$ , then  $\alpha$  is the obtuse angle.

## Radius of Curvature

The radius of curvature  $R$  of the curve  $y = f(x)$  at the point  $P(x, y)$  is

$$R = \frac{\{1 + [f'(x)]^2\}^{3/2}}{f''(x)}$$

In polar coordinates  $(\theta, r)$  the corresponding formula is

$$R = \frac{\left[ r^2 + \left( \frac{dr}{d\theta} \right)^2 \right]^{3/2}}{r^2 + 2 \left( \frac{dr}{d\theta} \right)^2 - r \frac{d^2r}{d\theta^2}}$$

The *curvature*  $K$  is  $1/R$ .

## Relative Maxima and Minima

The function  $f$  has a relative maximum at  $x = a$  if  $f(a) \geq f(a+c)$  for all values of  $c$  (positive or negative) that are sufficiently near zero. The function  $f$  has a relative minimum at  $x = b$  if  $f(b) \leq f(b+c)$  for all values of  $c$  that are sufficiently close to zero. If the function  $f$  is defined on the

closed interval  $x_1 \leq x \leq x_2$  and has a relative maximum or minimum at  $x = a$ , where  $x_1 < a < x_2$ , and if the derivative  $f'(x)$  exists at  $x = a$ , then  $f'(a) = 0$ . It is noteworthy that a relative maximum or minimum may occur at a point where the derivative does not exist. Further, the derivative may vanish at a point that is neither a maximum nor a minimum for the function. Values of  $x$  for which  $f'(x) = 0$  are called "critical values." To determine whether a critical value of  $x$ , say  $x_c$ , is a relative maximum or minimum for the function at  $x_c$ , one may use the second derivative test:

1. If  $f''(x_c)$  is positive,  $f(x_c)$  is a minimum.
2. If  $f''(x_c)$  is negative,  $f(x_c)$  is a maximum.
3. If  $f''(x_c)$  is zero, no conclusion may be made.

The sign of the derivative as  $x$  advances through  $x_c$  may also be used as a test. If  $f'(x)$  changes from positive to zero to negative, then a maximum occurs at  $x_c$ , whereas a change in  $f'(x)$  from negative to zero to positive indicates a minimum. If  $f'(x)$  does not change sign as  $x$  advances through  $x_c$ , then the point is neither a maximum nor a minimum.

## Points of Inflection of a Curve

The sign of the second derivative of  $f$  indicates whether the graph of  $y = f(x)$  is concave upward or concave downward:

$f''(x) > 0$ : concave upward

$f''(x) < 0$ : concave downward

A point of the curve at which the direction of concavity changes is called a point of inflection (Fig. 196.2). Such a point may occur where  $f''(x) = 0$  or where  $f''(x)$  becomes infinite. More precisely, if the function  $y = f(x)$  and its first derivative  $y' = f'(x)$  are continuous in the interval  $a \leq x \leq b$ , and if  $y'' = f''(x)$  exists in  $a < x < b$ , then the graph of  $y = f(x)$  for  $a < x < b$  is concave upward if  $f''(x)$  is positive and concave downward if  $f''(x)$  is negative.

**Figure 196.2** Point of inflection.

## Taylor's Formula

If  $f$  is a function that is continuous on an interval that contains  $a$  and  $x$ , and if its first  $(n+1)$

derivatives are continuous on this interval, then

$$f(x) = f(a) + f'(a)(x-a) + \frac{f''(a)}{2!}(x-a)^2 + \frac{f'''(a)}{3!}(x-a)^3 \\ + \cdots + \frac{f^{(n)}(a)}{n!}(x-a)^n + R$$

where  $R$  is called the *remainder*. There are various common forms of the remainder:  
*Lagrange's Form*

$$R = f^{(n+1)}(\beta) \cdot \frac{(x-a)^{n+1}}{(n+1)!}, \quad \beta \text{ between } a \text{ and } x$$

*Cauchy's Form*

$$R = f^{(n+1)}(\beta) \cdot \frac{(x-a)^n(x-a)}{n!}, \quad \beta \text{ between } a \text{ and } x$$

*Integral Form*

$$R = \int_a^x \frac{(x-t)^n}{n!} f^{(n+1)}(t) dt$$

## Indeterminant Forms

If  $f(x)$  and  $g(x)$  are continuous in an interval that includes  $x = a$ , and if  $f(a) = 0$  and  $g(a) = 0$ , the limit  $\lim_{x \rightarrow a} [f(x)/g(x)]$  takes the form "0/0", called an *indeterminant form*. *L'Hôpital's rule* is

$$\lim_{x \rightarrow a} \frac{f(x)}{g(x)} = \lim_{x \rightarrow a} \frac{f'(x)}{g'(x)}$$

Similarly, it may be shown that if  $f(x) \rightarrow \infty$  and  $g(x) \rightarrow \infty$  as  $x \rightarrow a$ , then

$$\lim_{x \rightarrow a} \frac{f(x)}{g(x)} = \lim_{x \rightarrow a} \frac{f'(x)}{g'(x)}$$

(The above holds for  $x \rightarrow \infty$ .)

## Examples

$$\lim_{x \rightarrow 0} \frac{\sin x}{x} = \lim_{x \rightarrow 0} \frac{\cos x}{1} = 1$$

$$\lim_{x \rightarrow \infty} \frac{x^2}{e^x} = \lim_{x \rightarrow \infty} \frac{2x}{e^x} = \lim_{x \rightarrow \infty} \frac{2}{e^x} = 0$$

## Numerical Methods

1. *Newton's method* for approximating roots of the equation  $f(x) = 0$ : A first estimate  $x_1$  of the root is made; then, provided that  $f'(x_1) \neq 0$ , a better approximation is  $x_2$ :

$$x_2 = x_1 - \frac{f(x_1)}{f'(x_1)}$$

The process may be repeated to yield a third approximation,  $x_3$ , to the root:

$$x_3 = x_2 - \frac{f(x_2)}{f'(x_2)}$$

provided  $f'(x_2)$  exists. The process may be repeated. (In certain rare cases the process will not converge.)

2. *Trapezoidal rule for areas* (Fig. 196.3): For the function  $y = f(x)$  defined on the interval  $(a, b)$  and positive there, take  $n$  equal subintervals of width  $\Delta x = (b - a)/n$ . The area bounded by the curve between  $x = a$  and  $x = b$  [or definite integral of  $f(x)$ ] is approximately the sum of trapezoidal areas, or

$$A \sim \left(\frac{1}{2}y_0 + y_1 + y_2 + \cdots + y_{n-1} + \frac{1}{2}y_n\right)(\Delta x)$$

Estimation of the error ( $E$ ) is possible if the second derivative can be obtained:

$$E = \frac{b-a}{12} f''(c)(\Delta x)^2$$

where  $c$  is some number between  $a$  and  $b$ .

**Figure 196.3** Trapezoidal rule for area.

## Functions of Two Variables

For the function of two variables, denoted  $z = f(x, y)$ , if  $y$  is held constant, say at  $y = y_1$ , then the resulting function is a function of  $x$  only. Similarly,  $x$  may be held constant at  $x_1$ , to give the resulting function of  $y$ .

### The Gas Laws

A familiar example is afforded by the ideal gas law relating the pressure  $p$ , the volume  $V$ , and the absolute temperature  $T$  of an ideal gas:

$$pV = nRT$$

where  $n$  is the number of moles and  $R$  is the gas constant per mole,  $8.31 \text{ (J} \cdot \text{K}^{-1} \cdot \text{mole}^{-1})$ . By rearrangement, any one of the three variables may be expressed as a function of the other two. Further, either one of these two may be held constant. If  $T$  is held constant, then we get the form known as Boyle's law:

$$p = kV^{-1} \quad (\text{Boyle's law})$$

where we have denoted  $nRT$  by the constant  $k$  and, of course,  $V > 0$ . If the pressure remains constant, we have Charles' law:

$$V = bT \quad (\text{Charles' law})$$

where the constant  $b$  denotes  $nR/p$ . Similarly, volume may be kept constant:

$$p = aT$$

where now the constant, denoted  $a$ , is  $nR/V$ .

## Partial Derivatives

The physical example afforded by the ideal gas law permits clear interpretations of processes in which one of the variables is held constant. More generally, we may consider a function  $z = f(x,y)$  defined over some region of the  $xy$  plane in which we hold one of the two coordinates, say  $y$ , constant. If the resulting function of  $x$  is differentiable at a point  $(x,y)$ , we denote this derivative by one of the notations

$$f_x, \quad \delta f/dx, \quad \delta z/dx$$

called the *partial derivative with respect to  $x$* . Similarly, if  $x$  is held constant and the resulting function of  $y$  is differentiable, we get the *partial derivative with respect to  $y$* , denoted by one of the following:

$$f_y, \quad \delta f/dy, \quad \delta z/dy$$

### Example.

Given  $z = x^4y^3 - y \sin x + 4y$ , then

$$\delta z/dx = 4(xy)^3 - y \cos x$$

$$\delta z/dy = 3x^4y^2 - \sin x + 4$$

## 196.4 Integral Calculus

---

### Indefinite Integral

If  $F(x)$  is differentiable for all values of  $x$  in the interval  $(a, b)$  and satisfies the equation  $dy/dx = f(x)$ , then  $F(x)$  is an integral of  $f(x)$  with respect to  $x$ . The notation is  $F(x) = \int f(x) dx$  or, in differential form,  $dF(x) = f(x) dx$ .

For any function  $F(x)$  that is an integral of  $f(x)$ , it follows that  $F(x) + C$  is also an integral. We thus write

$$\int f(x) dx = F(x) + C$$

### Definite Integral

Let  $f(x)$  be defined on the interval  $[a, b]$  which is partitioned by points  $x_1, x_2, \dots, x_j, \dots, x_{n-1}$  between  $a = x_0$  and  $b = x_n$ . The  $j$ th interval has length  $\Delta x_j = x_j - x_{j-1}$ , which may vary with  $j$ . The sum  $\sum_{j=1}^n f(v_j) \Delta x_j$ , where  $v_j$  is arbitrarily chosen in the  $j$ th subinterval, depends on the numbers  $x_0, \dots, x_n$  and the choice of the  $v$  as well as  $f$ ; but if such sums approach a common value as all  $\Delta x$  approach zero, then this value is the definite integral of  $f$  over the interval  $(a, b)$  and is denoted  $\int_a^b f(x) dx$ . The *fundamental theorem of integral calculus* states that

$$\int_a^b f(x) dx = F(b) - F(a),$$

where  $F$  is any continuous indefinite integral of  $f$  in the interval  $(a, b)$ .

### Properties

$$\int_a^b [f_1(x) + f_2(x) + \dots + f_j(x)] dx = \int_a^b f_1(x) dx + \int_a^b f_2(x) dx + \dots + \int_a^b f_j(x) dx$$

$$\int_a^b c f(x) dx = c \int_a^b f(x) dx, \quad \text{if } c \text{ is a constant}$$

$$\int_a^b f(x) dx = - \int_b^a f(x) dx$$

$$\int_a^b f(x) dx = \int_a^c f(x) dx + \int_c^b f(x) dx$$

## Common Applications of the Definite Integral

### Area (Rectangular Coordinates)

Given the function  $y = f(x)$  such that  $y > 0$  for all  $x$  between  $a$  and  $b$ , the area bounded by the curve  $y = f(x)$ , the  $x$  axis, and the vertical lines  $x = a$  and  $x = b$  is

$$A = \int_a^b f(x) dx$$

### Length of Arc (Rectangular Coordinates)

Given the smooth curve  $f(x, y) = 0$  from point  $(x_1, y_1)$  to point  $(x_2, y_2)$ , the length between these points is

$$L = \int_{x_1}^{x_2} \sqrt{1 + (dy/dx)^2} dx$$

$$L = \int_{y_1}^{y_2} \sqrt{1 + (dx/dy)^2} dy$$

### Mean Value of a Function

The mean value of a function  $f(x)$  continuous on  $[a, b]$  is

$$\frac{1}{(b-a)} \int_a^b f(x) dx$$

### Area (Polar Coordinates)

Given the curve  $r = f(\theta)$ , continuous and nonnegative for  $\theta_1 \leq \theta \leq \theta_2$ , the area enclosed by this curve and the radial lines  $\theta = \theta_1$  and  $\theta = \theta_2$  is given by

$$A = \int_{\theta_1}^{\theta_2} \frac{1}{2} [f(\theta)]^2 d\theta$$

### Length of Arc (Polar Coordinates)

Given the curve  $r = f(\theta)$  with continuous derivative  $f'(\theta)$  on  $\theta_1 \leq \theta \leq \theta_2$ , the length of arc from  $\theta = \theta_1$  to  $\theta = \theta_2$  is

$$L = \int_{\theta_1}^{\theta_2} \sqrt{[f(\theta)]^2 + [f'(\theta)]^2} d\theta$$

### Volume of Revolution

Given a function  $y = f(x)$  continuous and nonnegative on the interval  $(a, b)$ , when the region bounded by  $f(x)$  between  $a$  and  $b$  is revolved about the  $x$  axis, the volume of revolution is

$$V = \pi \int_a^b [f(x)]^2 dx$$

### Surface Area of Revolution(Revolution about the $x$ axis, between $a$ and $b$ )

If the portion of the curve  $y = f(x)$  between  $x = a$  and  $x = b$  is revolved about the  $x$  axis, the area  $A$  of the surface generated is given by the following:

$$A = \int_a^b 2\pi f(x) \{1 + [f'(x)]^2\}^{1/2} dx$$

### Work

If a variable force  $f(x)$  is applied to an object in the direction of motion along the  $x$  axis between  $x = a$  and  $x = b$ , the work done is

$$W = \int_a^b f(x) dx$$

## Cylindrical and Spherical Coordinates

1. Cylindrical coordinates (Fig. 196.4):

$$x = r \cos \theta$$

$$y = r \sin \theta$$

Element of volume  $dV = r dr d\theta dz$  .

2. Spherical coordinates (Fig. 196.5):

$$x = \rho \sin \phi \cos \theta$$

$$y = \rho \sin \phi \sin \theta$$

$$z = \rho \cos \phi$$

Element of volume  $dV = \rho^2 \sin \phi d\rho d\phi d\theta$  .

**Figure 196.4** Cylindrical coordinates.

**Figure 196.5** Spherical coordinates.

## Double Integration

The evaluation of a double integral of  $f(x, y)$  over a plane region  $R$ ,

$$\iint_R f(x, y) dA$$

is practically accomplished by iterated (repeated) integration. For example, suppose that a vertical straight line meets the boundary of  $R$  in at most two points so that there is an upper boundary,  $y = y_2(x)$ , and a lower boundary,  $y = y_1(x)$ . Also, it is assumed that these functions are continuous from  $a$  to  $b$  (see [Fig. 196.6](#)). Then

$$\iint_R f(x, y) dA = \int_a^b \left( \int_{y_1(x)}^{y_2(x)} f(x, y) dy \right) dx$$

If  $R$  has left-hand boundary,  $x = x_1(y)$ , and a right-hand boundary,  $x = x_2(y)$ , which are continuous from  $c$  to  $d$  (the extreme values of  $y$  in  $R$ ), then

$$\iint_R f(x, y) dA = \int_c^d \left( \int_{x_1(y)}^{x_2(y)} f(x, y) dx \right) dy$$

Such integrations are sometimes more convenient in polar coordinates,  $x = r \cos \theta$ ,  $y = r \sin \theta$ ,  $dA = r dr d\theta$ .

**Figure 196.6** Region  $R$  bounded by  $y_2(x)$  and  $y_1(x)$ .

## Surface Area and Volume by Double Integration

For the surface given by  $z = f(x, y)$ , which projects onto the closed region  $R$  of the  $xy$  plane, one may calculate the volume  $V$  bounded above by the surface and below by  $R$ , and the surface area  $S$  by the following:

$$V = \int \int_R z \, dA = \int \int_R f(x, y) \, dx \, dy$$

$$S = \int \int_R [1 + (\delta z / \delta x)^2 + (\delta z / \delta y)^2]^{1/2} \, dx \, dy$$

[In polar coordinates,  $(r, \theta)$ , we replace  $dA$  by  $r \, dr \, d\theta$  .]

## Centroid

The centroid of a region  $R$  of the  $xy$  plane is a point  $(x', y')$  where

$$x' = \frac{1}{A} \int \int_R x \, dA, \quad y' = \frac{1}{A} \int \int_R y \, dA$$

and  $A$  is the area of the region.

**Example.** For the circular sector of angle  $2\alpha$  and radius  $R$ , the area  $A$  is  $\alpha R^2$ ; the integral needed for  $x'$ , expressed in polar coordinates, is

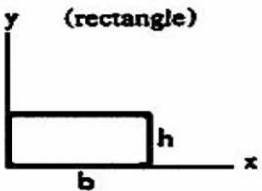

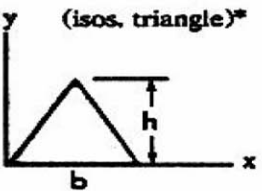

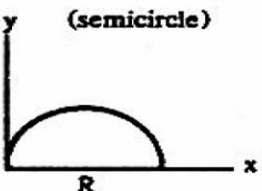

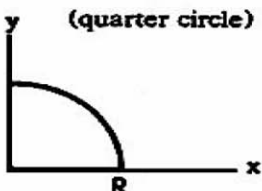

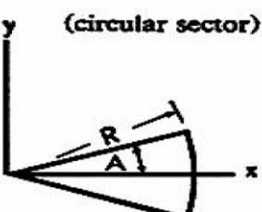

$$\begin{aligned} \int \int x \, dA &= \int_{-\alpha}^{\alpha} \int_0^R (r \cos \theta) r \, dr \, d\theta \\ &= \left[ \frac{R^3}{3} \sin \theta \right]_{-\alpha}^{+\alpha} = \frac{2}{3} R^3 \sin \alpha \end{aligned}$$

and thus,

$$x' = \frac{\frac{2}{3}R^3 \sin \alpha}{\alpha R^2} = \frac{2}{3}R \frac{\sin \alpha}{\alpha}$$

Centroids of some common regions are shown in [Table 196.1](#).

**Table 196.1** Centroids

	Area	$x'$	$y'$
Rectangle (rectangle) 	$bh$	$b/2$	$h/2$
Isosceles triangle* (isos. triangle)* 	$bh/2$	$b/2$	$h/3$
Semicircle (semicircle) 	$\pi R^2/2$	$R$	$4R/3\pi$
Quarter circle (quarter circle) 	$\pi R^2/4$	$4R/3\pi$	$4R/3\pi$
Circular sector (circular sector) 	$R^2 A$	$2R \sin A/3A$	0

\* $y' = h/3$  for any triangle of altitude  $h$ .

## 196.5 Special Functions

---

### Hyperbolic Functions

$$\sinh x = \frac{e^x - e^{-x}}{2}$$

$$\operatorname{csch} x = \frac{1}{\sinh x}$$

$$\cosh x = \frac{e^x + e^{-x}}{2}$$

$$\operatorname{sech} x = \frac{1}{\cosh x}$$

$$\tanh x = \frac{e^x - e^{-x}}{e^x + e^{-x}}$$

$$\operatorname{ctnh} x = \frac{1}{\tanh x}$$

$$\sinh(-x) = -\sinh x$$

$$\operatorname{ctnh}(-x) = -\operatorname{ctnh} x$$

$$\cosh(-x) = \cosh x$$

$$\operatorname{sech}(-x) = \operatorname{sech} x$$

$$\tanh(-x) = -\tanh x$$

$$\operatorname{csch}(-x) = -\operatorname{csch} x$$

$$\tanh x = \frac{\sinh x}{\cosh x}$$

$$\operatorname{ctnh} x = \frac{\cosh x}{\sinh x}$$

$$\cosh^2 x - \sinh^2 x = 1$$

$$\cosh^2 x = \frac{1}{2}(\cosh 2x + 1)$$

$$\sinh^2 x = \frac{1}{2}(\cosh 2x - 1)$$

$$\operatorname{ctnh}^2 x - \operatorname{csch}^2 x = 1$$

$$\operatorname{csch}^2 x - \operatorname{sech}^2 x = \operatorname{csch}^2 x \operatorname{sech}^2 x$$

$$\tanh^2 x + \operatorname{sech}^2 x = 1$$

$$\sinh(x + y) = \sinh x \cosh y + \cosh x \sinh y$$

$$\cosh(x + y) = \cosh x \cosh y + \sinh x \sinh y$$

$$\sinh(x - y) = \sinh x \cosh y - \cosh x \sinh y$$

$$\cosh(x - y) = \cosh x \cosh y - \sinh x \sinh y$$

$$\tanh(x + y) = \frac{\tanh x + \tanh y}{1 + \tanh x \tanh y}$$

$$\tanh(x - y) = \frac{\tanh x - \tanh y}{1 - \tanh x \tanh y}$$

## Bessel Functions

Bessel functions, also called cylindrical functions, arise in many physical problems as solutions of the differential equation

$$x^2 y'' + xy' + (x^2 - n^2)y = 0$$

which is known as Bessel's equation. Certain solutions, known as *Bessel functions of the first kind of order  $n$* , are given by

$$J_n(x) = \sum_{k=0}^{\infty} \frac{(-1)^k}{k! \Gamma(n+k+1)} \left(\frac{x}{2}\right)^{n+2k}$$

$$J_{-n}(x) = \sum_{k=0}^{\infty} \frac{(-1)^k}{k! \Gamma(-n+k+1)} \left(\frac{x}{2}\right)^{-n+2k}$$

In the above it is noteworthy that the gamma function must be defined for the negative argument  $q$ :  $\Gamma(q) = \Gamma(q+1)/q$ , provided that  $q$  is not a negative integer. When  $q$  is a negative integer,  $1/\Gamma(q)$  is defined to be zero. The functions  $J_{-n}(x)$  and  $J_n(x)$  are solutions of Bessel's equation for all real  $n$ . It is seen, for  $n = 1, 2, 3, \dots$ , that

$$J_{-n}(x) = (-1)^n J_n(x)$$

and, therefore, these are not independent; hence, a linear combination of these is not a general solution. When, however,  $n$  is not a positive integer, a negative integer, or zero, the linear combination with arbitrary constants  $c_1$  and  $c_2$ ,

$$y = c_1 J_n(x) + c_2 J_{-n}(x)$$

is the general solution of the Bessel differential equation.

The zero-order function is especially important as it arises in the solution of the heat equation (for a "long" cylinder):

$$J_0(x) = 1 - \frac{x^2}{2^2} + \frac{x^4}{2^2 4^2} - \frac{x^6}{2^2 4^2 6^2} + \dots$$

while the following relations show a connection to the trigonometric functions:

$$J_{1/2}(x) = \left[ \frac{2}{\pi x} \right]^{1/2} \sin x$$

$$J_{-1/2}(x) = \left[ \frac{2}{\pi x} \right]^{1/2} \cos x$$

The following recursion formula gives  $J_{n+1}(x)$  for any order in terms of lower-order functions:

$$\frac{2n}{x} J_n(x) = J_{n-1}(x) + J_{n+1}(x)$$

## Legendre Polynomials

If Laplace's equation,  $\nabla^2 V = 0$ , is expressed in spherical coordinates, it is

$$r^2 \sin \theta \frac{\delta^2 V}{\delta r^2} + 2r \sin \theta \frac{\delta V}{\delta r} + \sin \theta \frac{\delta^2 V}{\delta \theta^2} + \cos \theta \frac{\delta V}{\delta \theta} + \frac{1}{\sin \theta} \frac{\delta^2 V}{\delta \phi^2} = 0$$

and any of its solutions,  $V(r, \theta, \phi)$ , are known as *spherical harmonics*. The solution as a product

$$V(r, \theta, \phi) = R(r)\Theta(\theta)$$

which is independent of  $\phi$ , leads to

$$\sin^2 \theta \Theta'' + \sin \theta \cos \theta \Theta' + [n(n+1) \sin^2 \theta] \Theta = 0$$

Rearrangement and substitution of  $x = \cos \theta$  leads to

$$(1-x^2) \frac{d^2 \Theta}{dx^2} - 2x \frac{d\Theta}{dx} + n(n+1) \Theta = 0$$

known as *Legendre's equation*. Important special cases are those in which  $n$  is zero or a positive integer, and, for such cases, Legendre's equation is satisfied by polynomials called Legendre polynomials,  $P_n(x)$ . A short list of Legendre polynomials, expressed in terms of  $x$  and  $\cos \theta$ , is given below. These are given by the following general formula:

$$P_n(x) = \sum_{j=0}^L \frac{(-1)^j (2n-2j)!}{2^n j! (n-j)! (n-2j)!} x^{n-2j}$$

where  $L = n/2$  if  $n$  is even and  $L = (n-1)/2$  if  $n$  is odd.

$$P_0(x) = 1$$

$$P_1(x) = x$$

$$P_2(x) = \frac{1}{2}(3x^2 - 1)$$

$$P_3(x) = \frac{1}{2}(5x^3 - 3x)$$

$$P_4(x) = \frac{1}{8}(35x^4 - 30x^2 + 3)$$

$$P_5(x) = \frac{1}{8}(63x^5 - 70x^3 + 15x)$$

$$P_0(\cos \theta) = 1$$

$$P_1(\cos \theta) = \cos \theta$$

$$P_2(\cos \theta) = \frac{1}{4}(3 \cos 2\theta + 1)$$

$$P_3(\cos \theta) = \frac{1}{8}(5 \cos 3\theta + 3 \cos \theta)$$

$$P_4(\cos \theta) = \frac{1}{64}(35 \cos 4\theta + 20 \cos 2\theta + 9)$$

Additional Legendre polynomials may be determined from the *recursion formula*

$$(n+1)P_{n+1}(x) - (2n+1)xP_n(x) + nP_{n-1}(x) = 0 \quad (n = 1, 2, \dots)$$

or the *Rodrigues formula*

$$P_n(x) = \frac{1}{2^n n!} \frac{d^n}{dx^n} (x^2 - 1)^n$$

## Laguerre Polynomials

Laguerre polynomials, denoted  $L_n(x)$ , are solutions of the differential equation

$$xy'' + (1-x)y' + ny = 0$$

and are given by

$$L_n(x) = \sum_{j=0}^n \frac{(-1)^j}{j!} C_{(n,j)} x^j \quad (n = 0, 1, 2, \dots)$$

Thus,

$$L_0(x) = 1$$

$$L_1(x) = 1 - x$$

$$L_2(x) = 1 - 2x + \frac{1}{2}x^2$$

$$L_3(x) = 1 - 3x + \frac{3}{2}x^2 - \frac{1}{6}x^3$$

Additional Laguerre polynomials may be obtained from the recursion formula

$$(n+1)L_{n+1}(x) - (2n+1-x)L_n(x) + nL_{n-1}(x) = 0$$

## Hermite Polynomials

The Hermite polynomials, denoted  $H_n(x)$ , are given by

$$H_0 = 1, \quad H_n(x) = (-1)^n e^{x^2} \frac{d^n e^{-x^2}}{dx^n}, \quad (n = 1, 2, \dots)$$

and are solutions of the differential equation

$$y'' - 2xy' + 2ny = 0 \quad (n = 0, 1, 2, \dots)$$

The first few Hermite polynomials are

$$H_0 = 1$$

$$H_1(x) = 2x$$

$$H_2(x) = 4x^2 - 2$$

$$H_3(x) = 8x^3 - 12x$$

$$H_4(x) = 16x^4 - 48x^2 + 12$$

Additional Hermite polynomials may be obtained from the relation

$$H_{n+1}(x) = 2xH_n(x) - H'_n(x)$$

where prime denotes differentiation with respect to  $x$ .

## Orthogonality

A set of functions  $\{f_n(x)\}$  ( $n = 1, 2, \dots$ ) is orthogonal in an interval  $(a, b)$  with respect to a given weight function  $w(x)$  if

$$\int_a^b w(x) f_m(x) f_n(x) dx = 0 \quad \text{when } m \neq n$$

The following polynomials are orthogonal on the given interval for the given  $w(x)$  :

Legendre polynomials:	$P_n(x)$	$w(x) = 1$ $a = -1, b = 1$
Laguerre polynomials:	$L_n(x)$	$w(x) = \exp(-x)$ $a = 0, b = \infty$
Hermite polynomials:	$H_n(x)$	$w(x) = \exp(-x^2)$ $a = -\infty, b = \infty$

The Bessel functions of order  $n$ ,  $J_n(\lambda_1 x), J_n(\lambda_2 x), \dots$ , are orthogonal with respect to  $w(x) = x$  over the interval  $(0, c)$  provided that the  $\lambda_i$  are the positive roots of  $J_n(\lambda c) = 0$  :

$$\int_0^c x J_n(\lambda_j x) J_n(\lambda_k x) dx = 0 \quad (j \neq k)$$

where  $n$  is fixed and  $n \geq 0$ .

## Functions with $x^2/a^2 \pm y^2/b^2$

### Elliptic Paraboloid

(Fig. 196.7)

$$z = c(x^2/a^2 + y^2/b^2)$$

$$x^2/a^2 + y^2/b^2 - z/c = 0$$

**Figure 196.7** Elliptic paraboloid. (a)  $a = 0.5, b = 1.0, c = -1.0$ ; viewpoint = (5,-6,4). (b)  $a = 1.0, b = 1.0, c = -2.0$ ; viewpoint = (5,-6,4).

### Hyperbolic Paraboloid (Commonly Called *Saddle*)

(Fig. 196.8)

$$z = c(x^2/a^2 - y^2/b^2)$$

$$x^2/a^2 - y^2/b^2 - z/c = 0$$

**Figure 196.8** Hyperbolic paraboloid. (a)  $a = 0.50$ ,  $b = 0.5$ ,  $c = 1.0$ ; viewpoint = (4,-6,4). (b)  $a = 1.00$ ,  $b = 0.5$ ,  $c = 1.0$ ; viewpoint = (4,-6,4).

### Elliptic Cylinder

(Fig. 196.9)

$$1 = x^2/a^2 + y^2/b^2$$

$$x^2/a^2 + y^2/b^2 - 1 = 0$$

**Figure 196.9** Elliptic cylinder.  $a = 1.0$ ,  $b = 1.0$ ; viewpoint = (4,-5,2).

**Hyperbolic Cylinder**  
(Fig. 196.10)

$$1 = x^2/a^2 - y^2/b^2$$

$$x^2/a^2 - y^2/b^2 - 1 = 0$$

**Figure 196.10** Hyperbolic cylinder.  $a = 1.0$ ,  $b = 1.0$ ; viewpoint = (4,-6,3).

## Functions with $(x^2/a^2 + y^2/b^2 \pm c^2)^{1/2}$

### Sphere

(Fig. 196.11)

$$z = (1 - x^2 - y^2)^{1/2}$$

$$x^2 + y^2 + z^2 - 1 = 0$$

**Figure 196.11** Sphere. Viewpoint = (4,-5,2).

### Ellipsoid

(Fig. 196.12)

$$z = c(1 - x^2/a^2 - y^2/b^2)^{1/2}$$

$$x^2/a^2 + y^2/b^2 + z^2/c^2 - 1 = 0$$

**Figure 196.12** Ellipsoid. (a)  $a = 1.00$ ,  $b = 1.00$ ,  $c = 0.5$ ; viewpoint = (4,-5,2). (b)  $a = 0.50$ ,  $b = 0.50$ ,  $c = 1.0$ ; viewpoint = (4,-5,2).

*Special cases:*

$a = b > c$  gives oblate spheroid

$a = b < c$  gives prolate spheroid

## Cone

(Fig. 196.13)

$$z = (x^2 + y^2)^{1/2}$$

$$x^2 + y^2 - z^2 = 0$$

**Figure 196.13** Cone. Viewpoint = (4,-5,2).

**Elliptic Cone (Circular Cone if  $a = b$ )**  
(Fig. 196.14)

$$z = c(x^2/a^2 + y^2/b^2)^{1/2}$$

$$x^2/a^2 + y^2/b^2 - z^2/c^2 = 0$$

**Figure 196.14** Elliptic cone. (a)  $a = 0.5$ ,  $b = 0.5$ ,  $c = 1.00$ ; viewpoint = (4,-5,2). (b)  $a = 1.0$ ,  $b = 1.0$ ,  $c = 0.50$ ; viewpoint = (4,-5,2).

(a)

(b)

## Hyperboloid of One Sheet

(Fig. 196.15)

$$z = c(x^2/a^2 + y^2/b^2 - 1)^{1/2}$$

$$x^2/a^2 + y^2/b^2 - z^2/c^2 - 1 = 0$$

**Figure 196.15** Hyperboloid of one sheet. (a)  $a = 0.1, b = 0.1, c = 0.2; \pm z = c\sqrt{15}$ ; viewpoint = (4,-5,2).  
(b)  $a = 0.2, b = 0.2, c = 0.2; \pm z = c\sqrt{15}$ ; viewpoint = (4,-5,2).

(a)

(b)

## Hyperboloid of Two Sheets

(Fig. 196.16)

$$z = c(x^2/a^2 + y^2/b^2 + 1)^{1/2}$$

$$x^2/a^2 + y^2/b^2 - z^2/c^2 + 1 = 0$$

**Figure 196.16** Hyperboloid of two sheets. (a)  $a = 0.125$ ,  $b = 0.125$ ,  $c = 0.2$ ;  $\pm z = c\sqrt{17}$ ; viewpoint =  $(4, -5, 2)$ . (b)  $a = 0.25$ ,  $b = 0.25$ ,  $c = 0.2$ ;  $\pm z = c\sqrt{17}$ ; viewpoint =  $(4, -5, 2)$ .

## CALCULATING MACHINE

*William S. Burroughs*

*Patented August 21, 1888*

*#388,116*

An excerpt:

My invention relates to that class of apparatus used for mechanically assisting arithmetic calculations; and my invention consists in the combination, with one or more registers, of a series of independent keys and intervening connections construed, arranged, and operating, as fully specified hereinafter, so as to indicate upon the register the sum of any series of numbers by the proper manipulation of the keys, and also so as to print or permanently record the final result.

Burroughs had invented the adding machine. He and some St. Louis investors formed the American Arithmometer Company to market the machine. Improved versions were developed through the 1890's and Burroughs died in Alabama in 1898 after more than 1000 machines had been sold. In 1905, the company was renamed the Burroughs Adding Machine Company and moved its headquarters to Detroit, Michigan, where it became a force in the computer industry in 1950's and 1960's. Burroughs Corporation merged with Sperry in 1986 to become UniSys.

## 197.1 Basic Definitions

---

A *matrix*  $\mathbf{A}$  is a rectangular array of numbers (real or complex):

$$\mathbf{A} = \begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1m} \\ a_{21} & a_{22} & \cdots & a_{2m} \\ \vdots & & & \\ a_{n1} & a_{n2} & \cdots & a_{nm} \end{bmatrix}$$

The *size* of the matrix is said to be  $n \times m$ . The  $1 \times m$  matrices  $[a_{i1} \quad a_{i2} \quad \cdots \quad a_{im}]$  are called *rows* of  $\mathbf{A}$ , and the  $n \times 1$  matrices

$$\begin{bmatrix} a_{1j} \\ a_{2j} \\ \vdots \\ a_{nj} \end{bmatrix}$$

are called *columns* of  $\mathbf{A}$ . An  $n \times m$  matrix thus consists of  $n$  rows and  $m$  columns;  $a_{ij}$  denotes the *element*, or *entry*, of  $\mathbf{A}$  in the  $i$ th row and  $j$ th column. A matrix consisting of just one row is called a *row vector*, whereas a matrix of just one column is called a *column vector*. The elements of a vector are frequently called *components* of the vector. When the size of the matrix is clear from the

context, we sometimes write  $\mathbf{A} = (a_{ij})$ .

A matrix with the same number of rows as columns is a *square* matrix, and the number of rows and columns is the *order* of the matrix. The diagonal of an  $n \times n$  square matrix  $\mathbf{A}$  from  $a_{11}$  to  $a_{nn}$  is called the *main*, or *principal*, *diagonal*. The word *diagonal* with no modifier usually means the main diagonal. The *transpose* of a matrix  $\mathbf{A}$  is the matrix that results from interchanging the rows and columns of  $\mathbf{A}$ . It is usually denoted by  $\mathbf{A}^T$ . A matrix  $\mathbf{A}$  such that  $\mathbf{A} = \mathbf{A}^T$  is said to be *symmetric*. The *conjugate transpose* of  $\mathbf{A}$  is the matrix that results from replacing each element of  $\mathbf{A}^T$  by its complex conjugate, and is usually denoted by  $\mathbf{A}^H$ . A matrix such that  $\mathbf{A} = \mathbf{A}^H$  is said to be *Hermitian*.

A square matrix  $\mathbf{A} = (a_{ij})$  is *lower triangular* if  $a_{ij} = 0$  for  $j > i$  and is *upper triangular* if  $a_{ij} = 0$  for  $j < i$ . A matrix that is both upper and lower triangular is a *diagonal* matrix. The  $n \times n$  *identity matrix* is the  $n \times n$  diagonal matrix in which each element of the main diagonal is 1. It is traditionally denoted  $\mathbf{I}_n$ , or simply  $\mathbf{I}$  when the order is clear from the context.

## 197.2 Algebra of Matrices

---

The sum and difference of two matrices  $\mathbf{A}$  and  $\mathbf{B}$  are defined whenever  $\mathbf{A}$  and  $\mathbf{B}$  have the same size. In that case  $\mathbf{C} = \mathbf{A} \pm \mathbf{B}$  is defined by  $\mathbf{C} = (c_{ij}) = (a_{ij} \pm b_{ij})$ . The product  $t\mathbf{A}$  of a scalar  $t$  (real or complex number) and a matrix  $\mathbf{A}$  is defined by  $t\mathbf{A} = (ta_{ij})$ . If  $\mathbf{A}$  is an  $n \times m$  matrix and  $\mathbf{B}$  is an  $m \times p$  matrix, the product  $\mathbf{C} = \mathbf{AB}$  is defined to be the  $n \times p$  matrix  $\mathbf{C} = (c_{ij})$  given by  $c_{ij} = \sum_{k=1}^m a_{ik}b_{kj}$ . Note that the product of an  $n \times m$  matrix and an  $m \times p$  matrix is an  $n \times p$  matrix, and the product is defined only when the number of columns of the first factor is the same as the number of rows of the second factor. Matrix multiplication is, in general, associative:  $\mathbf{A}(\mathbf{BC}) = (\mathbf{AB})\mathbf{C}$ . It also distributes over addition (and subtraction):

$$\mathbf{A}(\mathbf{B} + \mathbf{C}) = \mathbf{AB} + \mathbf{AC} \quad \text{and} \quad (\mathbf{A} + \mathbf{B})\mathbf{C} = \mathbf{AC} + \mathbf{BC}$$

It is, however, not in general true that  $\mathbf{AB} = \mathbf{BA}$ , even in case both products are defined. It is clear that  $(\mathbf{A} + \mathbf{B})^T = \mathbf{A}^T + \mathbf{B}^T$  and  $(\mathbf{A} + \mathbf{B})^H = \mathbf{A}^H + \mathbf{B}^H$ . It is also true, but not so obvious perhaps, that  $(\mathbf{AB})^T = \mathbf{B}^T\mathbf{A}^T$  and  $(\mathbf{AB})^H = \mathbf{B}^H\mathbf{A}^H$ .

The  $n \times n$  identity matrix  $\mathbf{I}$  has the property that  $\mathbf{IA} = \mathbf{AI} = \mathbf{A}$  for every  $n \times n$  matrix  $\mathbf{A}$ . If  $\mathbf{A}$  is square, and if there is a matrix  $\mathbf{B}$  such that  $\mathbf{AB} = \mathbf{BA} = \mathbf{I}$ , then  $\mathbf{B}$  is called the *inverse* of  $\mathbf{A}$  and is denoted  $\mathbf{A}^{-1}$ . This terminology and notation are justified by the fact that a matrix can have at most one inverse. A matrix having an inverse is said to be *invertible*, or *nonsingular*, while a matrix not having an inverse is said to be *noninvertible*, or *singular*. The product of two invertible matrices is invertible and, in fact,  $(\mathbf{AB})^{-1} = \mathbf{B}^{-1}\mathbf{A}^{-1}$ . The sum of two invertible matrices is, obviously, not necessarily invertible.

## 197.3 Systems of Equations

---

The system of  $n$  linear equations in  $m$  unknowns

$$\begin{aligned}
a_{11}x_1 + a_{12}x_2 + a_{13}x_3 + \cdots + a_{1m}x_m &= b_1 \\
a_{21}x_1 + a_{22}x_2 + a_{23}x_3 + \cdots + a_{2m}x_m &= b_2 \\
&\vdots \\
a_{n1}x_1 + a_{n2}x_2 + a_{n3}x_3 + \cdots + a_{nm}x_m &= b_n
\end{aligned}$$

may be written  $\mathbf{Ax} = \mathbf{b}$ , where  $\mathbf{A} = (a_{ij})$ ,  $\mathbf{x} = [x_1 \ x_2 \ \cdots \ x_m]^T$ , and  $\mathbf{b} = [b_1 \ b_2 \ \cdots \ b_n]^T$ . Thus  $\mathbf{A}$  is an  $n \times m$  matrix, and  $\mathbf{x}$  and  $\mathbf{b}$  are column vectors of the appropriate sizes.

The matrix  $\mathbf{A}$  is called the *coefficient matrix* of the system. Let us first suppose the coefficient matrix is square; that is, there are an equal number of equations and unknowns. If  $\mathbf{A}$  is upper triangular, it is quite easy to find all solutions of the system. The  $i$ th equation will contain only the unknowns  $x_i, x_{i+1}, \dots, x_n$ , and one simply solves the equations in reverse order: the last equation is solved for  $x_n$ ; the result is substituted into the  $(n-1)$ st equation, which is then solved for  $x_{n-1}$ ; these values of  $x_n$  and  $x_{n-1}$  are substituted in the  $(n-2)$ th equation, which is solved for  $x_{n-2}$ , and so on. This procedure is known as *back substitution*.

The strategy for solving an arbitrary system is to find an upper-triangular system equivalent with it and solve this upper-triangular system using back substitution. First suppose the element  $a_{11} \neq 0$ . We may rearrange the equations to ensure this, unless, of course the first column of  $\mathbf{A}$  is all 0s. In this case proceed to the next step, to be described later. For each  $i \geq 2$  let  $m_{i1} = a_{i1}/a_{11}$ . Now replace the  $i$ th equation by the result of multiplying the first equation by  $m_{i1}$  and subtracting the new equation from the  $i$ th equation. Thus,

$$a_{i1}x_1 + a_{i2}x_2 + a_{i3}x_3 + \cdots + a_{im}x_m = b_i$$

is replaced by

$$0 \cdot x_1 + (a_{i2} + m_{i1}a_{12})x_2 + (a_{i3} + m_{i1}a_{13})x_3 + \cdots + (a_{im} + m_{i1}a_{1m})x_m = b_i + m_{i1}b_1$$

After this is done for all  $i = 2, 3, \dots, n$ , there results the equivalent system

$$\begin{aligned}
a_{11}x_1 + a_{12}x_2 + a_{13}x_3 + \cdots + a_{1n}x_n &= b_1 \\
0 \cdot x_1 + a'_{22}x_2 + a'_{23}x_3 + \cdots + a'_{2n}x_n &= b'_2 \\
0 \cdot x_1 + a'_{32}x_2 + a'_{33}x_3 + \cdots + a'_{3n}x_n &= b'_3 \\
&\vdots \\
0 \cdot x_1 + a'_{n2}x_2 + a'_{n3}x_3 + \cdots + a'_{nn}x_n &= b'_n
\end{aligned}$$

in which all entries in the first column below  $a_{11}$  are 0. (Note that if all entries in the first column were 0 to begin with, then  $a_{11} = 0$  also.) This procedure is now repeated for the  $(n-1) \times (n-1)$  system

$$\begin{aligned}
a'_{22}x_2 + a'_{23}x_3 + \cdots + a'_{2n}x_n &= b'_2 \\
a'_{32}x_2 + a'_{33}x_3 + \cdots + a'_{3n}x_n &= b'_3 \\
&\vdots \\
a'_{n2}x_2 + a'_{n3}x_3 + \cdots + a'_{nn}x_n &= b'_n
\end{aligned}$$

to obtain an equivalent system in which all entries of the coefficient matrix below  $a'_{22}$  are 0. Continuing, we obtain an upper-triangular system  $\mathbf{U}\mathbf{x} = \mathbf{c}$  equivalent with the original system. This procedure is known as *Gaussian elimination*. The numbers  $m_{ij}$  are known as the *multipliers*.

Essentially the same procedure may be used in case the coefficient matrix is not square. If the coefficient matrix is not square, we may make it square by appending either rows or columns of 0s as needed. Appending rows of 0s and appending 0s to make  $\mathbf{b}$  have the appropriate size is equivalent to appending equations  $0 = 0$  to the system. Clearly the new system has precisely the same solutions as the original system. Appending columns of 0s and adjusting the size of  $\mathbf{x}$  appropriately yields a new system with additional unknowns, each appearing only with coefficient 0, thus not affecting the solutions of the original system. In either case we may assume the coefficient matrix is square, and apply the Gauss elimination procedure.

Suppose the matrix  $\mathbf{A}$  is invertible. Then if there were no row interchanges in carrying out the above Gauss elimination procedure, we have the *LU factorization* of the matrix  $\mathbf{A}$ :

$$\mathbf{A} = \mathbf{L}\mathbf{U}$$

where  $\mathbf{U}$  is the upper-triangular matrix produced by elimination and  $\mathbf{L}$  is the lower-triangular matrix given by

$$\mathbf{L} = \begin{bmatrix} 1 & 0 & \cdots & \cdots & 0 \\ m_{21} & 1 & 0 & \cdots & 0 \\ \vdots & & \ddots & & \\ m_{n1} & m_{n2} & \cdots & & 1 \end{bmatrix}$$

A *permutation*  $\mathbf{P}_{ij}$  matrix is an  $n \times n$  matrix such that  $\mathbf{P}_{ij}\mathbf{A}$  is the matrix that results from exchanging row  $i$  and  $j$  of the matrix  $\mathbf{A}$ . The matrix  $\mathbf{P}_{ij}$  is the matrix that results from exchanging rows  $i$  and  $j$  of the identity matrix. A product  $\mathbf{P}$  of such matrices  $\mathbf{P}_{ij}$  is called a *permutation* matrix. If row interchanges are required in the Gauss elimination procedure, then we have the factorization

$$\mathbf{P}\mathbf{A} = \mathbf{L}\mathbf{U}$$

where  $\mathbf{P}$  is the permutation matrix giving the required row exchanges.

## 197.4 Vector Spaces

The collection of all column vectors with  $n$  real components is *Euclidean  $n$ -space*, and is denoted  $\mathbf{R}^n$ . The collection of column vectors with  $n$  complex components is denoted  $\mathbf{C}^n$ . We shall use *vector space* to mean either  $\mathbf{R}^n$  or  $\mathbf{C}^n$ . In discussing the space  $\mathbf{R}^n$ , the word *scalar* will mean a real number, and in discussing the space  $\mathbf{C}^n$ , it will mean a complex number. A subset  $\mathbf{S}$  of a vector space is a *subspace* such that if  $\mathbf{u}$  and  $\mathbf{v}$  are vectors in  $\mathbf{S}$ , and if  $c$  is any scalar, then  $\mathbf{u} + \mathbf{v}$  and  $c\mathbf{u}$  are in  $\mathbf{S}$ . We shall sometimes use the word *space* to mean a subspace. If  $B = \{\mathbf{v}_1, \mathbf{v}_2, \dots, \mathbf{v}_k\}$  is a collection of vectors in a vector space, then the set  $\mathbf{S}$  consisting of all vectors  $c_1\mathbf{v}_1 + c_2\mathbf{v}_2 + \dots + c_m\mathbf{v}_m$  for all scalars  $c_1, c_2, \dots, c_m$  is a subspace, called the *span* of  $B$ . A collection  $\{\mathbf{v}_1, \mathbf{v}_2, \dots, \mathbf{v}_m\}$  of vectors  $c_1\mathbf{v}_1 + c_2\mathbf{v}_2 + \dots + c_m\mathbf{v}_m$  is a *linear combination* of  $B$ . If  $\mathbf{S}$  is a subspace and  $B = \{\mathbf{v}_1, \mathbf{v}_2, \dots, \mathbf{v}_m\}$  is a subset of  $\mathbf{S}$  such that  $\mathbf{S}$  is the span of  $B$ , then  $B$  is said to *span*  $\mathbf{S}$ .

A collection  $\{\mathbf{v}_1, \mathbf{v}_2, \dots, \mathbf{v}_m\}$  of  $n$ -vectors is *linearly dependent* if there exist scalars  $c_1, c_2, \dots, c_m$ , not all zero, such that  $c_1\mathbf{v}_1 + c_2\mathbf{v}_2 + \dots + c_m\mathbf{v}_m = \mathbf{0}$ . A collection of vectors that is not linearly dependent is said to be *linearly independent*. The modifier *linearly* is frequently omitted, and we speak simply of dependent and independent collections. A linearly independent collection of vectors in a space  $\mathbf{S}$  that spans  $\mathbf{S}$  is a *basis* of  $\mathbf{S}$ . Every basis of a space  $\mathbf{S}$  contains the same number of vectors; this number is the *dimension* of  $\mathbf{S}$ . The dimension of the space consisting of only the zero vector is 0. The collection  $B = \{\mathbf{e}_1, \mathbf{e}_2, \dots, \mathbf{e}_n\}$ , where  $\mathbf{e}_1 = [1, 0, 0, \dots, 0]^T$ ,  $\mathbf{e}_2 = [0, 1, 0, \dots, 0]^T$ , and so forth ( $\mathbf{e}_i$  has 1 as its  $i$ th component and zero for all other components) is a basis for the spaces  $\mathbf{R}^n$  and  $\mathbf{C}^n$ . This is the *standard basis* for these spaces. The dimension of these spaces is thus  $n$ . In a space  $\mathbf{S}$  of dimension  $n$ , no collection of fewer than  $n$  vectors can span  $\mathbf{S}$ , and no collection of more than  $n$  vectors in  $\mathbf{S}$  can be independent.

## 197.5 Rank and Nullity

The *column space* of an  $n \times m$  matrix  $\mathbf{A}$  is the subspace of  $\mathbf{R}^n$  or  $\mathbf{C}^n$  spanned by the columns of  $\mathbf{A}$ . The *row space* is the subspace of  $\mathbf{R}^m$  or  $\mathbf{C}^m$  spanned by the rows of  $\mathbf{A}$ . Note that for any vector  $\mathbf{x} = [x_1 \ x_2 \ \dots \ x_m]^T$ ,

$$\mathbf{Ax} = x_1 \begin{bmatrix} a_{11} \\ a_{21} \\ \vdots \\ a_{n1} \end{bmatrix} + x_2 \begin{bmatrix} a_{12} \\ a_{22} \\ \vdots \\ a_{n2} \end{bmatrix} + \dots + x_m \begin{bmatrix} a_{1m} \\ a_{2m} \\ \vdots \\ a_{nm} \end{bmatrix}$$

so that the column space is the collection of all vectors  $\mathbf{Ax}$ , and thus the system  $\mathbf{Ax} = \mathbf{b}$  has a solution if and only if  $\mathbf{b}$  is a member of the column space of  $\mathbf{A}$ .

The dimension of the column space is the *rank* of  $\mathbf{A}$ . The row space has the same dimension as the column space. The set of all solutions of the system  $\mathbf{Ax} = \mathbf{0}$  is a subspace called the *null space* of  $\mathbf{A}$ , and the dimension of this null space is the *nullity* of  $\mathbf{A}$ . A fundamental result in matrix theory is the fact that, for an  $n \times m$  matrix  $\mathbf{A}$ ,

$$\text{rank } \mathbf{A} + \text{nullity } \mathbf{A} = m$$

The difference of any two solutions of the linear system  $\mathbf{Ax} = \mathbf{b}$  is a member of the null space of  $\mathbf{A}$ . Thus this system has at most one solution if and only if the nullity of  $\mathbf{A}$  is zero. If the system is square (that is, if  $\mathbf{A}$  is  $n \times n$ ), then there will be a solution for every right-hand side  $\mathbf{b}$  if and only if the collection of columns of  $\mathbf{A}$  is linearly independent, which is the same as saying the rank of  $\mathbf{A}$  is  $n$ . In this case the nullity must be zero. Thus, for any  $\mathbf{b}$ , the square system  $\mathbf{Ax} = \mathbf{b}$  has exactly one solution if and only if  $\text{rank } \mathbf{A} = n$ . In other words the  $n \times n$  matrix  $\mathbf{A}$  is invertible if and only if  $\text{rank } \mathbf{A} = n$ .

## 197.6 Orthogonality and Length

The *inner product* of two vectors  $\mathbf{x}$  and  $\mathbf{y}$  is the scalar  $\mathbf{x}^H \mathbf{y}$ . The *length*, or *norm*,  $\|\mathbf{x}\|$ , of the vector  $\mathbf{x}$  is given by  $\|\mathbf{x}\| = \sqrt{\mathbf{x}^H \mathbf{x}}$ . A *unit vector* is a vector of norm 1. Two vectors  $\mathbf{x}$  and  $\mathbf{y}$  are *orthogonal* if  $\mathbf{x}^H \mathbf{y} = 0$ . A collection of vectors  $\{\mathbf{v}_1, \mathbf{v}_2, \dots, \mathbf{v}_m\}$  in a space  $\mathbf{S}$  is said to be an *orthonormal* collection if  $\mathbf{v}_i^H \mathbf{v}_j = 0$  for  $i \neq j$  and  $\mathbf{v}_i^H \mathbf{v}_i = 1$ . An orthonormal collection is necessarily linearly independent. If  $\mathbf{S}$  is a subspace (of  $\mathbb{R}^n$  or  $\mathbb{C}^n$ ) spanned by the orthonormal collection  $\{\mathbf{v}_1, \mathbf{v}_2, \dots, \mathbf{v}_m\}$ , then the *projection* of a vector  $\mathbf{x}$  onto  $\mathbf{S}$  is the vector

$$\text{proj}(\mathbf{x}; \mathbf{S}) = (\mathbf{x}^H \mathbf{v}_1) \mathbf{v}_1 + (\mathbf{x}^H \mathbf{v}_2) \mathbf{v}_2 + \dots + (\mathbf{x}^H \mathbf{v}_m) \mathbf{v}_m$$

The projection of  $\mathbf{x}$  onto  $\mathbf{S}$  minimizes the function  $f(\mathbf{y}) = \|\mathbf{x} - \mathbf{y}\|^2$  for  $\mathbf{y} \in \mathbf{S}$ . In other words the projection of  $\mathbf{x}$  onto  $\mathbf{S}$  is the vector in  $\mathbf{S}$  that is "closest" to  $\mathbf{x}$ .

If  $\mathbf{b}$  is a vector and  $\mathbf{A}$  is an  $n \times m$  matrix, then a vector  $\mathbf{x}$  minimizes  $\|\mathbf{b} - \mathbf{Ax}\|^2$  if and only if it is a solution of  $\mathbf{A}^H \mathbf{Ax} = \mathbf{A}^H \mathbf{b}$ . This system of equations is called the *system of normal equations* for the least-squares problem of minimizing  $\|\mathbf{b} - \mathbf{Ax}\|^2$ .

If  $\mathbf{A}$  is an  $n \times m$  matrix and  $\text{rank } \mathbf{A} = k$ , then there is a  $n \times k$  matrix  $\mathbf{Q}$  whose columns form an orthonormal basis for the column space of  $\mathbf{A}$  and a  $k \times m$  upper-triangular matrix  $\mathbf{R}$  of rank  $k$  such that

$$\mathbf{A} = \mathbf{QR}$$

This is called the *QR factorization* of  $\mathbf{A}$ . It now follows that  $\mathbf{x}$  minimizes  $\|\mathbf{b} - \mathbf{Ax}\|^2$  if and only if it is a solution of the upper-triangular system  $\mathbf{Rx} = \mathbf{Q}^H \mathbf{b}$ .

If  $\{\mathbf{w}_1, \mathbf{w}_2, \dots, \mathbf{w}_m\}$  is a basis for a space  $\mathbf{S}$ , the following procedure produces an orthonormal basis  $\{\mathbf{v}_1, \mathbf{v}_2, \dots, \mathbf{v}_m\}$  for  $\mathbf{S}$ .

Set  $\mathbf{v}_1 = \mathbf{w}_1 / \|\mathbf{w}_1\|$ .

Let  $\tilde{\mathbf{v}}_2 = \mathbf{w}_2 - \text{proj}(\mathbf{w}_2; \mathbf{S}_1)$ , where  $\mathbf{S}_1$  is the span of  $\{\mathbf{v}_1\}$ ; set  $\mathbf{v}_2 = \tilde{\mathbf{v}}_2 / \|\tilde{\mathbf{v}}_2\|$ .

Next, let  $\tilde{\mathbf{v}}_3 = \mathbf{w}_3 - \text{proj}(\mathbf{w}_3; \mathbf{S}_2)$ , where  $\mathbf{S}_2$  is the span of  $\{\mathbf{v}_1, \mathbf{v}_2\}$ ; set  $\mathbf{v}_3 = \tilde{\mathbf{v}}_3 / \|\tilde{\mathbf{v}}_3\|$ .

And so on:  $\tilde{\mathbf{v}}_i = \mathbf{w}_i - \text{proj}(\mathbf{w}_i; \mathbf{S}_{i-1})$ , where  $\mathbf{S}_{i-1}$  is the span of  $\{\mathbf{v}_1, \mathbf{v}_2, \dots, \mathbf{v}_{i-1}\}$ ; set  $\mathbf{v}_i = \tilde{\mathbf{v}}_i / \|\tilde{\mathbf{v}}_i\|$ . This is the *Gram-Schmidt procedure*.

If the collection of columns of a square matrix is an orthonormal collection, the matrix is called a *unitary matrix*. In case the matrix is a real matrix, it is usually called an *orthogonal matrix*. A unitary matrix  $\mathbf{U}$  is invertible, and  $\mathbf{U}^{-1} = \mathbf{U}^H$ . (In the real case an orthogonal matrix  $\mathbf{Q}$  is invertible, and  $\mathbf{Q}^{-1} = \mathbf{Q}^T$ .)

## 197.7 Determinants

---

The *determinant* of a square matrix is defined inductively. First, suppose the determinant  $\det \mathbf{A}$  has been defined for all square matrices of order  $< n$ . Then

$$\det \mathbf{A} = a_{11} \mathbf{C}_{11} + a_{12} \mathbf{C}_{12} + \cdots + a_{1n} \mathbf{C}_{1n}$$

where the numbers  $\mathbf{C}_{ij}$  are *cofactors* of the matrix  $\mathbf{A}$ :

$$\mathbf{C}_{ij} = (-1)^{i+j} \det \mathbf{M}_{ij}$$

where  $\mathbf{M}_{ij}$  is the  $(n-1) \times (n-1)$  matrix obtained by deleting the  $i$ th row and  $j$ th column of  $\mathbf{A}$ . Now  $\det \mathbf{A}$  is defined to be the only entry of a matrix of order 1. Thus, for a matrix of order 2, we have

$$\det \begin{bmatrix} a & b \\ c & d \end{bmatrix} = ad - bc$$

There are many interesting but not obvious properties of determinants. It is true that

$$\det \mathbf{A} = a_{i1} \mathbf{C}_{i1} + a_{i2} \mathbf{C}_{i2} + \cdots + a_{in} \mathbf{C}_{in}$$

for any  $1 \leq i \leq n$ . It is also true that  $\det \mathbf{A} = \det \mathbf{A}^T$ , so that we have

$$\det \mathbf{A} = a_{1j} \mathbf{C}_{1j} + a_{2j} \mathbf{C}_{2j} + \cdots + a_{nj} \mathbf{C}_{nj}$$

for any  $1 \leq j \leq n$ .

If  $\mathbf{A}$  and  $\mathbf{B}$  are matrices of the same order, then  $\det \mathbf{AB} = (\det \mathbf{A})(\det \mathbf{B})$ , and the determinant of any identity matrix is 1. Perhaps the most important property of the determinant is the fact that a matrix is invertible if and only if its determinant is not zero.

## 197.8 Eigenvalues and Eigenvectors

---

If  $\mathbf{A}$  is a square matrix, and  $\mathbf{A}\mathbf{v} = \lambda\mathbf{v}$  for a scalar  $\lambda$  and a nonzero  $\mathbf{v}$ , then  $\lambda$  is an *eigenvalue* of  $\mathbf{A}$  and  $\mathbf{v}$  is an *eigenvector* of  $\mathbf{A}$  that *corresponds* to  $\lambda$ . Any nonzero linear combination of eigenvectors corresponding to the same eigenvalue  $\lambda$  is also an eigenvector corresponding to  $\lambda$ . The collection of all eigenvectors corresponding to a given eigenvalue  $\lambda$  is thus a subspace, called an *eigenspace* of  $\mathbf{A}$ . A collection of eigenvectors corresponding to different eigenvalues is

necessarily linear-independent. It follows that a matrix of order  $n$  can have at most  $n$  distinct eigenvectors. In fact, the eigenvalues of  $\mathbf{A}$  are the roots of the  $n$ th degree polynomial equation

$$\det(\mathbf{A} - \lambda \mathbf{I}) = 0$$

called the *characteristic equation* of  $\mathbf{A}$ . (Eigenvalues and eigenvectors are frequently called *characteristic values* and *characteristic vectors*.)

If the  $n$ th order matrix  $\mathbf{A}$  has an independent collection of  $n$  eigenvectors, then  $\mathbf{A}$  is said to have a *full set* of eigenvectors. In this case there is a set of eigenvectors of  $\mathbf{A}$  that is a basis for  $\mathbb{R}^n$  or, in the complex case,  $\mathbb{C}^n$ . In case there are  $n$  distinct eigenvalues of  $\mathbf{A}$ , then, of course,  $\mathbf{A}$  has a full set of eigenvectors. If there are fewer than  $n$  distinct eigenvalues, then  $\mathbf{A}$  may or may not have a full set of eigenvectors. If there is a full set of eigenvectors, then

$$\mathbf{D} = \mathbf{S}^{-1} \mathbf{A} \mathbf{S} \quad \text{or} \quad \mathbf{A} = \mathbf{S} \mathbf{D} \mathbf{S}^{-1}$$

where  $\mathbf{D}$  is a diagonal matrix with the eigenvalues of  $\mathbf{A}$  on the diagonal, and  $\mathbf{S}$  is a matrix whose columns are the full set of eigenvectors. If  $\mathbf{A}$  is symmetric, there are  $n$  real distinct eigenvalues of  $\mathbf{A}$  and the corresponding eigenvectors are orthogonal. There is thus an orthonormal collection of eigenvectors that span  $\mathbb{R}^n$ , and we have

$$\mathbf{A} = \mathbf{Q} \mathbf{D} \mathbf{Q}^T \quad \text{and} \quad \mathbf{D} = \mathbf{Q}^T \mathbf{A} \mathbf{Q}$$

where  $\mathbf{Q}$  is a real orthogonal matrix and  $\mathbf{D}$  is diagonal. For the complex case, if  $\mathbf{A}$  is Hermitian, we have

$$\mathbf{A} = \mathbf{U} \mathbf{D} \mathbf{U}^H \quad \text{and} \quad \mathbf{D} = \mathbf{U}^H \mathbf{A} \mathbf{U}$$

where  $\mathbf{U}$  is a unitary matrix and  $\mathbf{D}$  is a *real* diagonal matrix. (A Hermitian matrix also has  $n$  distinct real eigenvalues.)

## 198.1 Basic Definitions

---

A vector is a directed line segment, with two vectors being equal if they have the same length and the same direction. More precisely, a *vector* is an equivalence class of directed line segments, where two directed segments are equivalent if they have the same length and the same direction. The *length* of a vector is the common length of its directed segments, and the *angle between* vectors is the angle between any of their segments. The length of a vector  $\mathbf{u}$  is denoted  $|\mathbf{u}|$ . There is defined a distinguished vector having zero length, which is usually denoted  $\mathbf{0}$ . It is frequently useful to visualize a directed segment as an arrow; we then speak of the nose and the tail of the segment. The *sum*  $\mathbf{u} + \mathbf{v}$  of two vectors  $\mathbf{u}$  and  $\mathbf{v}$  is defined by taking directed segments from  $\mathbf{u}$  and  $\mathbf{v}$  and placing the tail of the segment representing  $\mathbf{v}$  at the nose of the segment representing  $\mathbf{u}$  and defining  $\mathbf{u} + \mathbf{v}$  to be the vector determined by the segment from the tail of the  $\mathbf{u}$  representative to the nose of the  $\mathbf{v}$  representative. It is easy to see that  $\mathbf{u} + \mathbf{v}$  is well defined and that  $\mathbf{u} + \mathbf{v} = \mathbf{v} + \mathbf{u}$ . Subtraction is the inverse operation of addition. Thus the *difference*  $\mathbf{u} - \mathbf{v}$  of two vectors is defined to be the vector that when added to  $\mathbf{v}$  gives  $\mathbf{u}$ . In other words, if we take a segment from  $\mathbf{u}$  and a segment from  $\mathbf{v}$  and place their tails together, the difference is the segment from the nose of  $\mathbf{v}$  to the nose of  $\mathbf{u}$ . The zero vector behaves as one might expect:  $\mathbf{u} + \mathbf{0} = \mathbf{u}$ , and  $\mathbf{u} - \mathbf{u} = \mathbf{0}$ . Addition is associative:  $\mathbf{u} + (\mathbf{v} + \mathbf{w}) = (\mathbf{u} + \mathbf{v}) + \mathbf{w}$ .

To distinguish them from vectors, the real numbers are called *scalars*. The product  $t\mathbf{u}$  of a scalar  $t$  and a vector  $\mathbf{u}$  is defined to be the vector having length  $|t||\mathbf{u}|$  and direction the same as  $\mathbf{u}$  if  $t > 0$ , the opposite direction if  $t < 0$ . If  $t = 0$ , then  $t\mathbf{u}$  is defined to be the zero vector. Note that  $t(\mathbf{u} + \mathbf{v}) = t\mathbf{u} + t\mathbf{v}$ , and  $(t + s)\mathbf{u} = t\mathbf{u} + s\mathbf{u}$ . From this it follows that  $\mathbf{u} - \mathbf{v} = \mathbf{u} + (-1)\mathbf{v}$ .

The *scalar product*  $\mathbf{u} \cdot \mathbf{v}$  of two vectors is  $|\mathbf{u}||\mathbf{v}| \cos \theta$ , where  $\theta$  is the angle between  $\mathbf{u}$  and  $\mathbf{v}$ .

The scalar product is frequently called the *dot product*. The scalar product distributes over addition :

$$\mathbf{u} \cdot (\mathbf{v} + \mathbf{w}) = \mathbf{u} \cdot \mathbf{v} + \mathbf{u} \cdot \mathbf{w}$$

and it is clear that  $(t\mathbf{u}) \cdot \mathbf{v} = t(\mathbf{u} \cdot \mathbf{v})$  . The *vector product*  $\mathbf{u} \times \mathbf{v}$  of two vectors is defined to be the vector perpendicular to both  $\mathbf{u}$  and  $\mathbf{v}$  and having length  $|\mathbf{u}||\mathbf{v}| \sin \theta$  , where  $\theta$  is the angle between  $\mathbf{u}$  and  $\mathbf{v}$ . The direction of  $\mathbf{u} \times \mathbf{v}$  is the direction a right-hand threaded bolt advances if the vector  $\mathbf{u}$  is rotated to  $\mathbf{v}$ . The vector product is frequently called the *cross product*. The vector product is both associative and distributive, but not commutative:  $\mathbf{u} \times \mathbf{v} = -\mathbf{v} \times \mathbf{u}$  .

## 198.2 Coordinate Systems

---

Suppose we have a right-handed Cartesian coordinate system in space. For each vector  $\mathbf{u}$ , we associate a point in space by placing the tail of a representative of  $\mathbf{u}$  at the origin and associating with  $\mathbf{u}$  the point at the nose of the segment. Conversely, associated with each point in space is the vector determined by the directed segment from the origin to that point. There is thus a one-to-one correspondence between the points in space and all vectors. The origin corresponds to the zero vector. The coordinates of the point associated with a vector  $\mathbf{u}$  are called *coordinates* of  $\mathbf{u}$ . One frequently refers to the vector  $\mathbf{u}$  and writes  $\mathbf{u} = (x, y, z)$  , which is, strictly speaking, incorrect, because the left side of this equation is a vector and the right side gives the coordinates of a point in space. What is meant is that  $(x, y, z)$  are the coordinates of the point associated with  $\mathbf{u}$  under the correspondence described. In terms of coordinates, for  $\mathbf{u} = (u_1, u_2, u_3)$  and  $\mathbf{v} = (v_1, v_2, v_3)$  , we have

$$\mathbf{u} + \mathbf{v} = (u_1 + v_1, u_2 + v_2, u_3 + v_3)$$

$$t\mathbf{u} = (tu_1, tu_2, tu_3)$$

$$\mathbf{u} \cdot \mathbf{v} = u_1 v_1 + u_2 v_2 + u_3 v_3$$

$$\mathbf{u} \times \mathbf{v} = (u_2 v_3 - v_2 u_3, u_3 v_1 - v_3 u_1, u_1 v_2 - v_1 u_2)$$

The *coordinate vectors*  $\mathbf{i}$ ,  $\mathbf{j}$ , and  $\mathbf{k}$  are the unit vectors  $\mathbf{i} = (1, 0, 0)$  ,  $\mathbf{j} = (0, 1, 0)$  , and  $\mathbf{k} = (0, 0, 1)$  . Any vector  $\mathbf{u} = (u_1, u_2, u_3)$  is thus a linear combination of these coordinate vectors:  $\mathbf{u} = u_1 \mathbf{i} + u_2 \mathbf{j} + u_3 \mathbf{k}$  . A convenient form for the vector product is the formal determinant

$$\mathbf{u} \times \mathbf{v} = \det \begin{bmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ u_1 & u_2 & u_3 \\ v_1 & v_2 & v_3 \end{bmatrix}$$

## 198.3 Vector Functions

---

A *vector function*  $\mathbf{F}$  of one variable is a rule that associates a vector  $\mathbf{F}(t)$  with each real number  $t$  in some set, called the *domain* of  $\mathbf{F}$ . The expression  $\lim_{t \rightarrow t_0} \mathbf{F}(t) = \mathbf{a}$  means that for any  $\varepsilon > 0$ , there is a  $\delta > 0$  such that  $|\mathbf{F}(t) - \mathbf{a}| < \varepsilon$  whenever  $0 < |t - t_0| < \delta$ . If  $\mathbf{F}(t) = [x(t), y(t), z(t)]$  and  $\mathbf{a} = (a_1, a_2, a_3)$ , then  $\lim_{t \rightarrow t_0} \mathbf{F}(t) = \mathbf{a}$  if and only if

$$\lim_{t \rightarrow t_0} x(t) = a_1$$

$$\lim_{t \rightarrow t_0} y(t) = a_2$$

$$\lim_{t \rightarrow t_0} z(t) = a_3$$

A vector function  $\mathbf{F}$  is *continuous* at  $t_0$  if  $\lim_{t \rightarrow t_0} \mathbf{F}(t) = \mathbf{F}(t_0)$ . The vector function  $\mathbf{F}$  is continuous at  $t_0$  if and only if each of the coordinates  $x(t)$ ,  $y(t)$ , and  $z(t)$  is continuous at  $t_0$ .

The function  $\mathbf{F}$  is *differentiable* at  $t_0$  if the limit

$$\lim_{h \rightarrow 0} \frac{1}{h} [\mathbf{F}(t+h) - \mathbf{F}(t)]$$

exists. This limit is called the *derivative* of  $\mathbf{F}$  at  $t_0$  and is usually written  $\mathbf{F}'(t_0)$ , or  $(d\mathbf{F}/dt)(t_0)$ .

The vector function  $\mathbf{F}$  is differentiable at  $t_0$  if and only if each of its coordinate functions is differentiable at  $t_0$ . Moreover,  $(d\mathbf{F}/dt)(t_0) = [(dx/dt)(t_0), (dy/dt)(t_0), (dz/dt)(t_0)]$ . The usual rules for derivatives of real valued functions all hold for vector functions. Thus if  $\mathbf{F}$  and  $\mathbf{G}$  are vector functions and  $s$  is a scalar function, then

$$\frac{d}{dt}(\mathbf{F} + \mathbf{G}) = \frac{d\mathbf{F}}{dt} + \frac{d\mathbf{G}}{dt}$$

$$\frac{d}{dt}(s\mathbf{F}) = s \frac{d\mathbf{F}}{dt} + \frac{ds}{dt} \mathbf{F}$$

$$\frac{d}{dt}(\mathbf{F} \cdot \mathbf{G}) = \mathbf{F} \cdot \frac{d\mathbf{G}}{dt} + \frac{d\mathbf{F}}{dt} \cdot \mathbf{G}$$

$$\frac{d}{dt}(\mathbf{F} \times \mathbf{G}) = \mathbf{F} \times \frac{d\mathbf{G}}{dt} + \frac{d\mathbf{F}}{dt} \times \mathbf{G}$$

If  $\mathbf{R}$  is a vector function defined for  $t$  in some interval, then, as  $t$  varies, with the tail of  $\mathbf{R}$  at the origin, the nose traces out some object  $C$  in space. For nice functions  $\mathbf{R}$ , the object  $C$  is a *curve*. If  $\mathbf{R}(t) = [x(t), y(t), z(t)]$ , then the equations

$$x = x(t)$$

$$y = y(t)$$

$$z = z(t)$$

are called *parametric equations* of  $C$ . At points where  $\mathbf{R}$  is differentiable, the derivative  $d\mathbf{R}/dt$  is a vector *tangent* to the curve. The unit vector  $\mathbf{T} = (d\mathbf{R}/dt)/|d\mathbf{R}/dt|$  is called the *unit tangent vector*. If  $\mathbf{R}$  is differentiable and if the length of the arc of curve described by  $\mathbf{R}$  between  $\mathbf{R}(a)$  and  $\mathbf{R}(t)$  is given by  $s(t)$ , then

$$\frac{ds}{dt} = \left| \frac{d\mathbf{R}}{dt} \right|$$

Thus the length  $L$  of the arc from  $\mathbf{R}(t_0)$  to  $\mathbf{R}(t_1)$  is

$$L = \int_{t_0}^{t_1} \frac{ds}{dt} dt = \int_{t_0}^{t_1} \left| \frac{d\mathbf{R}}{dt} \right| dt$$

The vector  $d\mathbf{T}/ds = (d\mathbf{T}/dt)/(ds/dt)$  is perpendicular to the unit tangent  $\mathbf{T}$ , and the number  $\kappa = |d\mathbf{T}/ds|$  is the *curvature* of  $C$ . The unit vector  $\mathbf{N} = (1/\kappa)(d\mathbf{T}/ds)$  is the *principal normal*. The vector  $\mathbf{B} = \mathbf{T} \times \mathbf{N}$  is the *binormal*, and  $d\mathbf{B}/ds = -\tau\mathbf{N}$ . The number  $\tau$  is the *torsion*. Note that  $C$  is a plane curve if and only if  $\tau$  is zero for all  $t$ .

A *vector function*  $\mathbf{F}$  of two variables is a rule that assigns a vector  $\mathbf{F}(s, t)$  to each point  $(s, t)$  in some subset of the plane, called the *domain* of  $\mathbf{F}$ . If  $\mathbf{R}(s, t)$  is defined for all  $(s, t)$  in some region  $D$  of the plane, then as the point  $(s, t)$  varies over  $D$ , with its tail at the origin, the nose of  $\mathbf{R}(s, t)$  traces out an object in space. For a nice function  $\mathbf{R}$ , this object is a *surface*,  $S$ . The partial derivatives  $(\partial\mathbf{R}/\partial s)(s, t)$  and  $(\partial\mathbf{R}/\partial t)(s, t)$  are tangent to the surface at  $\mathbf{R}(s, t)$ , and the vector  $(\partial\mathbf{R}/\partial s) \times (\partial\mathbf{R}/\partial t)$  is thus *normal* to the surface. Of course,  $(\partial\mathbf{R}/\partial t) \times (\partial\mathbf{R}/\partial s) = -(\partial\mathbf{R}/\partial s) \times (\partial\mathbf{R}/\partial t)$  is also normal to the surface and points in the direction opposite that of  $(\partial\mathbf{R}/\partial s) \times (\partial\mathbf{R}/\partial t)$ . By electing one of these normals, we are choosing an *orientation* of the surface. A surface can be oriented only if it has two sides, and the process of orientation consists of choosing which side is "positive" and which is "negative."

## 198.4 Gradient, Curl, and Divergence

If  $f(x, y, z)$  is a scalar field defined in some region  $D$ , the *gradient* of  $\mathbf{f}$  is the vector function

$$\text{grad } f = \frac{\partial f}{\partial x}\mathbf{i} + \frac{\partial f}{\partial y}\mathbf{j} + \frac{\partial f}{\partial z}\mathbf{k}$$

If  $\mathbf{F}(x, y, z) = F_1(x, y, z)\mathbf{i} + F_2(x, y, z)\mathbf{j} + F_3(x, y, z)\mathbf{k}$  is a vector field defined in some region  $D$ , then the *divergence* of  $\mathbf{F}$  is the scalar function

$$\operatorname{div} \mathbf{F} = \frac{\partial F_1}{\partial x} + \frac{\partial F_2}{\partial y} + \frac{\partial F_3}{\partial z}$$

The curl is the vector function

$$\operatorname{curl} \mathbf{F} = \left( \frac{\partial F_3}{\partial y} - \frac{\partial F_2}{\partial z} \right) \mathbf{i} + \left( \frac{\partial F_1}{\partial z} - \frac{\partial F_3}{\partial x} \right) \mathbf{j} + \left( \frac{\partial F_2}{\partial x} - \frac{\partial F_1}{\partial y} \right) \mathbf{k}$$

In terms of the vector operator *del*,  $\nabla = \mathbf{i}(\partial/\partial x) + \mathbf{j}(\partial/\partial y) + \mathbf{k}(\partial/\partial z)$ , we can write

$$\operatorname{grad} f = \nabla f$$

$$\operatorname{div} \mathbf{F} = \nabla \cdot \mathbf{F}$$

$$\operatorname{curl} \mathbf{F} = \nabla \times \mathbf{F}$$

The *Laplacian operator* is  $\operatorname{div}(\operatorname{grad}) = \nabla \cdot \nabla = \nabla^2 = (\partial^2/\partial x^2) + (\partial^2/\partial y^2) + (\partial^2/\partial z^2)$ .

## 198.5 Integration

---

Suppose  $C$  is a curve from the point  $(x_0, y_0, z_0)$  to the point  $(x_1, y_1, z_1)$  and is described by the vector function  $\mathbf{R}(t)$  for  $t_0 \leq t \leq t_1$ . If  $f$  is a scalar function (sometimes called a *scalar field*) defined on  $C$ , then the integral of  $f$  over  $C$  is

$$\int_C f(x, y, z) ds = \int_{t_0}^{t_1} f[\mathbf{R}(t)] \left| \frac{d\mathbf{R}}{dt} \right| dt$$

If  $\mathbf{F}$  is a vector function (sometimes called a *vector field*) defined on  $C$ , then the integral of  $\mathbf{F}$  over  $C$  is

$$\int_C \mathbf{F}(x, y, z) \cdot d\mathbf{R} = \int_{t_0}^{t_1} \mathbf{F}[\mathbf{R}(t)] \cdot \frac{d\mathbf{R}}{dt} dt$$

These integrals are called *line integrals*.

In case there is a scalar function  $f$  such that  $\mathbf{F} = \operatorname{grad} f$ , then the line integral

$$\int_C \mathbf{F}(x, y, z) \cdot d\mathbf{R} = f[\mathbf{R}(t_1)] - f[\mathbf{R}(t_0)]$$

The value of the integral thus depends only on the end points of the curve  $C$  and not on the curve  $C$

itself. The integral is said to be *path-independent*. The function  $f$  is called a *potential function* for the vector field  $\mathbf{F}$ , and  $\mathbf{F}$  is said to be a *conservative field*. A vector field  $\mathbf{F}$  with domain  $D$  is conservative if and only if the integral of  $\mathbf{F}$  around every closed curve in  $D$  is zero. If the domain  $D$  is simply connected (that is, every closed curve in  $D$  can be continuously deformed in  $D$  to a point), then  $\mathbf{F}$  is conservative if and only if  $\text{curl } \mathbf{F} = 0$  in  $D$ .

Suppose  $S$  is a surface described by  $\mathbf{R}(s, t)$  for  $(s, t)$  in a region  $D$  of the plane. If  $f$  is a scalar function defined on  $D$ , then the integral of  $f$  over  $S$  is given by

$$\int_S f(x, y, z) dS = \int_D \int f[\mathbf{R}(s, t)] \left| \frac{\partial \mathbf{R}}{\partial s} \times \frac{\partial \mathbf{R}}{\partial t} \right| ds dt$$

If  $\mathbf{F}$  is a vector function defined on  $S$ , and if an orientation for  $S$  is chosen, then the integral of  $\mathbf{F}$  over  $S$ , sometimes called the **flux** of  $\mathbf{F}$  through  $S$ , is

$$\int_S \mathbf{F}(x, y, z) \cdot d\mathbf{S} = \int_D \int \mathbf{F}[\mathbf{R}(s, t)] \cdot \left( \frac{\partial \mathbf{R}}{\partial s} \times \frac{\partial \mathbf{R}}{\partial t} \right) ds dt$$

## 198.6 Integral Theorems

---

Suppose  $\mathbf{F}$  is a vector field with a closed domain  $D$  bounded by the surface  $S$  oriented so that the normal points out from  $D$ . Then the *divergence theorem* states that

$$\int_D \int \int \text{div } \mathbf{F} dV = \int_S \int \mathbf{F} \cdot d\mathbf{S}$$

If  $S$  is an orientable surface bounded by a closed curve  $C$ , the orientation of the closed curve  $C$  is chosen to be consistent with the orientation of the surface  $S$ . Then we have *Stokes's theorem*:

$$\int_S (\text{curl } \mathbf{F}) \cdot d\mathbf{S} = \oint_C \mathbf{F} \cdot d\mathbf{s}$$

## 199.1 Basic Definitions and Arithmetic

---

A *complex number* is an ordered pair  $z = (x, y)$  of real numbers  $x$  and  $y$ . The sum, difference, product, and quotient of two complex numbers  $z = (x, y)$  and  $w = (u, v)$  are defined by

$$z \pm w = (x \pm u, y \pm v)$$

$$zw = (xu - yv, xv + yu)$$

$$\frac{w}{z} = \left( \frac{xu + yv}{x^2 + y^2}, \frac{xv - yu}{x^2 + y^2} \right)$$

The *real part* of the complex number  $z = (x, y)$  is  $x$ , and the *imaginary part* of  $z$  is  $y$ . If  $z_1 = (a, 0)$  and  $z_2 = (b, 0)$ , then  $z_1 \pm z_2 = (a \pm b, 0)$ ,  $z_1 z_2 = (ab, 0)$ , and  $z_1 / z_2 = (a/b, 0)$ . Thus, for complex numbers with 0 imaginary part, complex arithmetic coincides with the usual arithmetic for real numbers, and we see that the complex numbers are an extension of the real numbers. In this case we write simply  $a$  for the complex number  $(a, 0)$ , and so on.

For the complex number  $i = (0, 1)$  we have that  $i^2 = (-1, 0) \equiv -1$ . Now note that for any  $z = (x, y)$ , it is true that

$$z = (x, y) = (x, 0) + (0, y) = x + iy$$

and the algebra of complex numbers reduces to the usual algebra for real numbers, together with

the fact that  $i^2 = -1$  .

The *conjugate* of a complex number  $z = x + iy$  is defined to be  $\bar{z} = x - iy$  . The *modulus* of  $z$  is the real number  $|z| = \sqrt{z\bar{z}} = \sqrt{x^2 + y^2}$  . We have the following properties of the conjugate and the modulus:

$$\overline{(z \pm w)} = \bar{z} \pm \bar{w}$$

$$\overline{zw} = \bar{z}\bar{w} \quad \text{and} \quad \overline{\left(\frac{w}{z}\right)} = \frac{\bar{w}}{\bar{z}}$$

$$|z + w| \leq |z| + |w|$$

$$|zw| = |z||w| \quad \text{and} \quad \left|\frac{w}{z}\right| = \frac{|w|}{|z|}$$

Considering  $z = (x, y)$  to be the rectangular coordinates of a point in the plane establishes a one-to-one correspondence between the set of all complex numbers and the points in the plane. We thus speak of points in the plane as being complex numbers. The usual Euclidean distance  $d(z, w)$  between the points  $z$  and  $w$  is then given by  $d(z, w) = |z - w|$  . Let  $(r, \theta)$  be polar coordinates of the point  $z = (x, y)$  . (We always assume  $r \geq 0$  .) Then  $r$  is, of course, simply  $|z|$ , the modulus of  $z$ . The number  $\theta$  is called an *argument* of  $z$  and is denoted  $\arg z$ . Thus,  $z = r(\cos \theta + i \sin \theta)$  . If  $w = s(\cos \vartheta + i \sin \vartheta)$  , then

$$zw = rs[\cos(\theta + \vartheta) + i \sin(\theta + \vartheta)]$$

$$\frac{z}{w} = \frac{r}{s}[\cos(\theta - \vartheta) + i \sin(\theta - \vartheta)]$$

$$z^n = r^n[\cos n\theta + i \sin n\theta]$$

Note that a complex number has an infinite number of arguments, and  $\arg z$  denotes any one of them. Any interval  $(a, b]$  of reals of length  $2\pi$  contains exactly one argument of  $z$ . The particular value of  $\arg z$  in the interval  $(-\pi, \pi]$  is called the *principal value of the argument* and is denoted  $\text{Arg } z$ .

## 199.2 Complex Functions

---

Let  $\mathbf{C}$  denote the set of all complex numbers (the *complex plane*). A set  $\mathbf{S} \subset \mathbf{C}$  is said to be a *neighborhood* of the point  $z_0$  if there is an  $r > 0$  such that  $z \in \mathbf{S}$  whenever  $|z_0 - z| < r$  . The point  $z_0$  is an *interior point* of  $\mathbf{S}$  in case  $\mathbf{S}$  is a neighborhood of  $z_0$ . A point  $z_0$  is called a *limit point* of a

set  $\mathbf{A}$  if every neighborhood of  $z_0$  meets  $\mathbf{A}$ . A set that is a neighborhood of each of its points is called an *open set*, and a set that contains all its limit points is called a *closed set*.

A function  $f$  from a subset of the complex numbers into the complex numbers is called a *complex function*. The statement that the *limit* of  $f$  at  $z_0$  is  $w_0$  means that for each  $\varepsilon > 0$ , there is a  $\delta > 0$  such that  $|f(z) - w_0| < \varepsilon$  whenever  $z$  is in the domain of  $f$  and  $|z - z_0| < \delta$ . We write

$$\lim_{z \rightarrow z_0} f(z) = w_0$$

Note that it is not required that  $z_0$  be in the domain of  $f$ .

The function  $f$  is *continuous* at the point  $z_0$  in its domain if  $\lim_{z \rightarrow z_0} f(z) = f(z_0)$ . If  $z_0$  is an interior point of the domain of  $f$ , then  $f$  is said to be *differentiable* at  $z_0$  if the limit

$$f'(z_0) = \lim_{z \rightarrow z_0} \frac{f(z) - f(z_0)}{z - z_0}$$

exists. The number  $f'(z_0)$  is the *derivative* of  $f$  at  $z_0$ .

A complex function of the form  $p(z) = a_n z^n + a_{n-1} z^{n-1} + \cdots + a_1 z + a_0$  is called a *polynomial*. A *rational function*  $r$  is the quotient of two polynomials:  $r(z) = p(z)/q(z)$ . A polynomial is continuous and differentiable at every complex number, and a rational function is continuous and differentiable everywhere except at those points  $z_0$  for which  $q(z_0) = 0$ .

## 199.3 Analytic Functions

---

A complex function  $f$  is *analytic* on an open set  $\mathbf{U}$  if it has a derivative at each point of  $\mathbf{U}$ . The function  $f$  is said to be analytic at the point  $z_0$  if it is analytic on some open set containing  $z_0$ . A function analytic on all of the complex plane is an *entire* function. If  $f(z) = u(x, y) + iv(x, y)$  is analytic in an open set  $\mathbf{U}$ , then the real and imaginary parts of  $f(z)$  satisfy the Cauchy-Riemann equations:

$$\frac{\partial u}{\partial x} = \frac{\partial v}{\partial y} \quad \text{and} \quad \frac{\partial u}{\partial y} = -\frac{\partial v}{\partial x}$$

and both  $u$  and  $v$  satisfy *Laplace's equation* in  $\mathbf{U}$ :

$$\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} = 0$$

A function that satisfies Laplace's equation in a domain  $\mathbf{U}$  is said to be *harmonic* in  $\mathbf{U}$ . Thus the real and imaginary parts of a function analytic in an open set are harmonic on the same set.

## 199.4 Integration

---

An integral of a complex function  $f$  is defined on a curve (or *contour*)  $C$  in the complex plane and is simply the line integral of  $f$  on  $C$ . Thus if  $z = \gamma(t)$ ,  $a \leq t \leq b$  defines a contour  $C$  from the point  $z_0 = \gamma(a)$  to the point  $z_1 = \gamma(b)$ , the *contour integral* of  $f$  along  $C$  is given by

$$\int_C f(z) dz = \int_a^b f(\gamma(t)) \gamma'(t) dt$$

All of the usual nice linearity properties of integrals hold for complex integrals. Thus,

$$\int_C [c_1 f(z) + c_2 g(z)] dz = c_1 \int_C f(z) dz + c_2 \int_C g(z) dz$$

for any complex numbers  $c_1$  and  $c_2$ . If  $C_1$  and  $C_2$  are contours, then  $\int_{C_1+C_2} f(z) dz$  is defined by

$$\int_{C_1+C_2} f(z) dz = \int_{C_1} f(z) dz + \int_{C_2} f(z) dz$$

A contour given by  $z = \gamma(t)$ ,  $a \leq t \leq b$  is called a *simple* contour if  $\gamma(t) \neq \gamma(s)$  for  $a < t, s < b$ , and  $t \neq s$ . A *closed* contour is a contour for which  $\gamma(a) = \gamma(b)$ . If  $C$  is given by  $z = \gamma(t)$ ,  $a \leq t \leq b$ , then  $-C$  is the contour given by  $z = \gamma(a + b - t)$ ,  $a \leq t \leq b$ . It is clear that

$$\int_{-C} f(z) dz = - \int_C f(z) dz$$

Suppose  $C$  is a simple closed contour and  $f$  is a function analytic at all points on and inside  $C$ . Then

$$\int_C f(z) dz = 0$$

This is the celebrated *Cauchy-Goursat theorem*.

An open connected set  $U$  such that every simple closed contour in  $U$  encloses only points of  $U$  is said to be *simply connected*. If  $z_0$  and  $z_1$  are points in a simply connected open set  $U$ , and if  $C_1$  and  $C_2$  are contours in  $U$  from  $z_0$  and  $z_1$ , then for any  $f$  analytic in  $U$ , it is true that

$$\int_{C_1} f(z) dz = \int_{C_2} f(z) dz$$

A simple closed contour  $C$  given by  $z = \gamma(t)$ ,  $a \leq t \leq b$  is *positively oriented* if, for  $z_0$  inside  $C$ , the argument  $\text{Arg}[\gamma(t) - z_0]$  increases as  $t$  goes from  $a$  to  $b$ . If  $f$  is analytic in simply connected region  $U$ , and if  $C$  is a positively oriented simple closed curve in  $U$ , then for every  $z_0$  in  $U$  that is not on  $C$ , we have

$$f(z_0) = \frac{1}{2\pi i} \int_C \frac{f(z)}{z - z_0} dz$$

This is the celebrated *Cauchy integral formula*. If  $f$  is analytic at a point  $z_0$ , then it has derivatives of all orders, and

$$f^{(n)}(z_0) = \frac{n!}{2\pi i} \int_C \frac{f(z)}{(z - z_0)^{n+1}} dz$$

If the function  $f$  is continuous on an open connected set  $\mathbf{U}$  and if

$$\int_C f(z) dz = 0$$

for every closed contour  $C$  in  $\mathbf{U}$ , then  $f$  is analytic on  $\mathbf{U}$ . This is *Morera's theorem*.

If  $f$  is analytic on an open set  $\mathbf{U}$ , the point  $z_0$  is in  $\mathbf{U}$ , and  $C_R$  is a circle in  $\mathbf{U}$  of radius  $r$  centered at  $z_0$  on which  $|f(z)| \leq M$ , then

$$|f^{(n)}(z_0)| \leq \frac{n!M}{r^n}$$

It follows from this that a bounded entire function must be constant.

## 199.5 Series

---

Let  $f$  be a function analytic in an open set  $\mathbf{U}$ , and let  $z_0$  be a point of  $\mathbf{U}$ . Then there is a unique power series  $\sum_{k=0}^{\infty} a_k(z - z_0)^k$  such that

$$f(z) = \sum_{k=0}^{\infty} a_k(z - z_0)^k$$

for all  $z$  in some neighborhood of  $z_0$ . This series is the *Taylor series* of  $f$  at  $z_0$  and converges to  $f(z)$  for all  $z$  inside a circle  $C$ , on which is found the singularity of  $f$  closest to  $z_0$ . The radius of  $C$  is called the *radius of convergence* of the series. This series may be differentiated term by term to obtain the Taylor series for the  $n$ th derivative of  $f$  at  $z_0$ :

$$f^{(n)}(z) = \sum_{k=n}^{\infty} k(k-1) \cdots (k-n+1) a_k(z - z_0)^{k-n}$$

The radius of convergence of this series is the same as that of the Taylor series for  $f$ . It follows easily that, for each  $n = 0, 1, 2, \dots$ , we have

$$a_n = \frac{1}{n!} f^{(n)}(z_0)$$

Let  $C_0$  and  $C_1$  be two concentric circles centered at a point  $z_0$ , with  $C_0$  having a smaller radius than  $C_1$ . Suppose the function  $f$  is analytic on an open set containing the two circles and the annular region between them. Then, for each point in the annular region bounded by the circles, we have

$$f(z) = \sum_{k=0}^{\infty} a_k (z - z_0)^k + \sum_{k=1}^{\infty} b_k (z - z_0)^{-k}$$

where

$$a_k = \frac{1}{2\pi i} \int_C \frac{f(z)}{(z - z_0)^{k+1}} dz$$

$$b_k = \frac{1}{2\pi i} \int_C \frac{f(z)}{(z - z_0)^{-k+1}} dz$$

for any positively oriented simply closed contour  $C$  around the annular region. This is a *Laurent series*. It is sometimes written

$$f(z) = \sum_{k=-\infty}^{\infty} c_k (z - z_0)^k$$

with

$$c_k = \frac{1}{2\pi i} \int_C \frac{f(z)}{(z - z_0)^{k+1}} dz$$

## 199.6 Singularities

---

Suppose that  $z_0$  is a singular point of the function  $f$  and  $f$  is analytic in a neighborhood of  $z_0$ . (Except, of course, at  $z_0$ .) Then  $z_0$  is called an *isolated singular point*, or an *isolated singularity*, of  $f$ . In case  $z_0$  is an isolated singular point of  $f$ , the Laurent series

$$f(z) = \sum_{k=-\infty}^{\infty} c_k (z - z_0)^k$$

represents  $f$  for all  $z$  such that  $0 < |z - z_0| < r$ , for some  $r > 0$ . If  $c_k = 0$  for all  $k \leq -1$ , then  $z_0$

is said to be a *removable* singularity. (The value of  $f$  at  $z_0$  can, in this case, be redefined to be  $c_0$ , and the function so defined is analytic at  $z_0$ .) If there is a negative integer  $N < -1$  such that  $c_k = 0$  for all  $k \leq N$ , then  $z_0$  is a *pole* of order  $p$ , where  $p$  is the largest positive integer for which  $c_{-p} \neq 0$ . A pole of order one is called a *simple pole*. An isolated singularity that is neither a removable singularity nor a pole is called an *essential* singularity. Thus,  $z_0$  is an essential singularity if, for every negative  $N$ , there is a  $k < N$  such that  $c_k \neq 0$ .

If  $z_0$  is an isolated singularity of the function  $f$ , then the coefficient  $c_{-1}$  in the Laurent series given is the *residue* of  $f$  at  $z_0$ . If  $z_0$  is a simple pole, then the residue of  $f$  at  $z_0$  is given by

$$\text{Res}(z_0) = \lim_{z \rightarrow z_0} (z - z_0) f(z)$$

If  $z_0$  is a pole of order  $p$ , then

$$\text{Res}(z_0) = \lim_{z \rightarrow z_0} \frac{1}{(p-1)!} \frac{d^{p-1}}{dz^{p-1}} [(z - z_0)^p f(z)]$$

The importance of the idea of the residue comes from *Cauchy's residue theorem*, which says that if  $C$  is a positively oriented simple closed contour and the function  $f$  is analytic on and inside  $C$  except at the points  $z_1, z_2, \dots, z_n$ , then

$$\int_C f(z) dz = 2\pi i \sum_{k=1}^n \text{Res}(z_k)$$

## 199.7 Conformal Mapping

We can regard a one-to-one complex function  $f$  on a region  $\mathbf{D}$  as defining a *mapping* from  $\mathbf{D}$  into the plane. In case  $f$  is analytic, this mapping is *conformal*; that is, angles are preserved. More importantly, such a mapping preserves the harmonic property of a function. Thus, if  $f$  is analytic and  $w = f(z) = u(x, y) + iv(x, y)$  maps a domain  $\mathbf{D}_z$  onto a domain  $\mathbf{D}_w$ , and if

$$\frac{\partial^2 \Phi(u, v)}{\partial u^2} + \frac{\partial^2 \Phi(u, v)}{\partial v^2} = 0 \text{ in } \mathbf{D}_w$$

then

$$\frac{\partial^2 \Theta(x, y)}{\partial x^2} + \frac{\partial^2 \Theta(x, y)}{\partial y^2} = 0 \text{ in } \mathbf{D}_z$$

where  $\Theta(x, y) = \Phi[u(x, y), v(x, y)]$ . Conformal mappings are useful in solving boundary value problems involving Laplace's equation in a region of the plane. The given region is mapped conformally to another region in which the solution is either known or easy to find.

## 200.1 First-Order Equations

## 200.2 Second-Order Equations

## 200.3 Linear Equations with Constant Coefficients

200.4 Generating Function ( $z$  Transform)**William F. Ames***Georgia Institute of Technology*

Difference equations are equations involving *discrete variables*. They appear as natural descriptions of natural phenomena and in the study of discretization methods for differential equations, which have continuous variables.

Let  $y_n = y(nh)$ , where  $n$  is an integer and  $h$  a real number. (One can think of measurements taken at equal intervals,  $h, 2h, 3h, \dots$ , and  $y_n$  describes these.) A typical equation is that describing the famous Fibonacci sequence— $y_{n+2} - y_{n+1} - y_n = 0$ . Another example is the equation  $y_{n+2} - 2zy_{n+1} + y_n = 0$ ,  $z \in C$ , which describes the Chebyshev polynomials.

**200.1 First-Order Equations**

The general first-order equation  $y_{n+1} = f(y_n)$ ,  $y_0 = y(0)$  is easily solved, for as many terms as are needed, by *iteration*. Then  $y_1 = f(y_0)$ ;  $y_2 = f(y_1)$ ,  $\dots$ . An example is the logistic equation  $y_{n+1} = ay_n(1 - y_n) = f(y_n)$ . The logistic equation has two fixed (critical or equilibrium) points where  $y_{n+1} = y_n$ . They are 0 and  $\bar{y} = (a - 1)/a$ . This has physical meaning only for  $a > 1$ . For  $1 < a < 3$  the equilibrium  $\bar{y}$  is asymptotically stable, and for  $a > 3$  there are two points  $y_1$  and  $y_2$ , called a *cycle of period two*, in which  $y_2 = f(y_1)$  and  $y_1 = f(y_2)$ . This study leads into chaos, which is outside our interest. By iteration, with  $y_0 = 1/2$ , we have  $y_1 = (a/2)(1/2) = a/2^2$ ,  $y_2 = a(a/2^2)(1 - a/2^2) = (a^2/2^2)(1 - a/2^2)$ ,  $\dots$ .

With a constant, the equation  $y_{n+1} = ay_n$  is solved by making the assumption  $y_n = A\lambda^n$  and finding  $\lambda$  so that the equation holds. Thus  $A\lambda^{n+1} = aA\lambda^n$ , and hence  $\lambda = 0$  or  $\lambda = a$  and  $A$  is arbitrary. Discarding the trivial solution 0 we find  $y_n = Aa^{n+1}$  is the desired solution. By using a method called the *variation of constants*, the equation  $y_{n+1} - ay_n = g_n$  has the solution  $y_n = y_0a^n + \sum_{j=0}^{n-1} g_ja^{n-j-1}$ , with  $y_0$  arbitrary.

In various applications we find the first-order equation of *Riccati type*  $y_n y_{n-1} + ay_n + by_{n-1} + c = 0$  where  $a$ ,  $b$ , and  $c$  are real constants. This equation can be transformed to a linear second-order equation by setting  $y_n = z_n/z_{n-1} - a$  to obtain

$z_{n+1} + (b+a)z_n + (c-ab)z_{n-1} = 0$  , which is solvable as described in the next section.

## 200.2 Second-Order Equations

The second-order linear equation with constant coefficients  $y_{n+2} + ay_{n+1} + by_n = f_n$  is solved by first solving the homogeneous equation (with right-hand side zero) and adding to that solution any solution of the inhomogeneous equation. The *homogeneous equation*  $y_{n+2} + ay_{n+1} + by_n = 0$  is solved by assuming  $y_n = \lambda^n$ , whereupon  $\lambda^{n+2} + a\lambda^{n+1} + b\lambda^n = 0$  or  $\lambda = 0$  (rejected) or  $\lambda^2 + a\lambda + b = 0$ . The roots of this quadratic are  $\lambda_1 = \frac{1}{2}(-a + \sqrt{a^2 - 4b})$ ,  $\lambda_2 = -\frac{1}{2}(a + \sqrt{a^2 - 4b})$  and the solution of the homogeneous equation is  $y_n = c_1\lambda_1^n + c_2\lambda_2^n$ . As an example consider the Fibonacci equation  $y_{n+2} - y_{n+1} - y_n = 0$ . The roots of  $\lambda^2 - \lambda - 1 = 0$  are  $\lambda_1 = \frac{1}{2}(1 + \sqrt{5})$ ,  $\lambda_2 = \frac{1}{2}(1 - \sqrt{5})$ , and the solution  $y_n = c_1[(1 + \sqrt{5})/2]^n + c_2[(1 - \sqrt{5})/2]^n$  is known as the *Fibonacci sequence*.

Many of the orthogonal polynomials of differential equations and numerical analysis satisfy a second-order difference equation (recurrence relation) involving a discrete variable, say  $n$ , and a continuous variable, say  $z$ . One such is the *Chebyshev equation*  $y_{n+2} - 2zy_{n+1} + y_n = 0$  with the initial conditions  $y_0 = 1$ ,  $y_1 = z$  (*first-kind* Chebyshev polynomials) and  $y_{-1} = 0$ ,  $y_0 = 1$  (*second-kind* Chebyshev polynomials). They are denoted  $T_n(z)$  and  $V_n(z)$ , respectively. By iteration we find

$$\begin{aligned} T_0(z) &= 1, & T_1(z) &= z, & T_2(z) &= 2z^2 - 1, \\ T_3(z) &= 4z^3 - 3z, & T_4(z) &= 8z^4 - 8z^2 + 1 \\ V_0(z) &= 0, & V_1(z) &= 1, & V_2(z) &= 2z, \\ V_3(z) &= 4z^2 - 1, & V_4(z) &= 8z^3 - 4z \end{aligned}$$

and the general solution is  $y_n(z) = c_1T_n(z) + c_2V_{n-1}(z)$ .

## 200.3 Linear Equations with Constant Coefficients

The general  $k$ th-order linear equation with constant coefficients is  $\sum_{i=0}^k p_i y_{n+k-i} = g_n$ ,  $p_0 = 1$ . The solution to the corresponding homogeneous equation (obtained by setting  $g_n = 0$ ) is as follows. (a)  $y_n = \sum_{i=1}^k c_i \lambda_i^n$  if the  $\lambda_i$  are the distinct roots of the characteristic polynomial  $p(\lambda) = \sum_{i=0}^k p_i \lambda^{k-i} = 0$ . (b) If  $m_s$  is the multiplicity of the root  $\lambda_s$ , then the functions  $y_{n,s} = u_s(n)\lambda_s^n$ , where  $u_s(n)$  are polynomials in  $n$  whose degree does not exceed  $m_s - 1$ , are solutions of the equation. Then the general solution of the homogeneous equation is  $y_n = \sum_{i=1}^d a_i u_i(n)\lambda_i^n = \sum_{i=1}^d a_i \sum_{j=0}^{m_i-1} c_j n^j \lambda_i^n$ . To this solution one adds any particular solution to obtain the general solution of the general equation.

### Example 200.1

A model equation for the price  $p_n$  of a product, at the  $n$ th time, is

$p_n + \frac{b}{a}(1 + \rho)p_{n-1} - \frac{b}{a}\rho p_{n-2} + (s_0 - d_0)/a = 0$  . The equilibrium price is obtained by setting  $p_n = p_{n-1} = p_{n-2} = p_e$  , and one finds  $p_e = (d_0 - s_0)/(a + b)$  . The homogeneous equation has the characteristic polynomial  $\lambda^2 + (b/a)(1 + \rho)\lambda - (b/a)\rho = 0$  . With  $\lambda_1$  and  $\lambda_2$  as the roots the general solution of the full equation is  $p_n = c_1\lambda_1^n + c_2\lambda_2^n + p_e$  , since  $p_e$  is a solution of the full equation. This is one method for finding the solution of the nonhomogeneous equation.

## 200.4 Generating Function (z Transform)

An elegant way of solving linear difference equations with constant coefficients, among other applications, is by use of *generating functions* or, as an alternative, the  $z$  transform. The generating function of a sequence  $\{y_n\}$  ,  $n = 0, 1, 2, \dots$  , is the function  $f(x)$  given by the formal series  $f(x) = \sum_{n=0}^{\infty} y_n x^n$  . The  $z$  transform of the same sequence is  $z(x) = \sum_{n=0}^{\infty} y_n x^{-n}$  . Clearly,  $z(x) = f(1/x)$  . A table of some important sequences is given in [Table 200.1](#)

**Table 200.1** Important Sequences

$y_n$	$f(x)$	Convergence Domain
1	$(1 - x)^{-1}$	$ x  < 1$
$n$	$x(1 - x)^{-2}$	$ x  < 1$
$n^m$	$x p_m(x)(1 - x)^{-m-1}$	$ x  < 1$
$k^n$	$(1 - kx)^{-1}$	$ x  < k^{-1}$
$e^{an}$	$(1 - e^a x)^{-1}$	$ x  < e^{-a}$
$k^n \cos an$	$\frac{1 - kx \cos a}{1 - 2kx \cos a + k^2 x^2}$	$ x  < k^{-1}$
$k^n \sin an$	$\frac{1 - kx \sin a}{1 - 2kx \cos a + k^2 x^2}$	$ x  < k^{-1}$
$\binom{n}{m}$	$x^m (1 - x)^{-m-1}$	$ x  < 1$
$\binom{k}{n}$	$(1 + x)^k$	$ x  < 1$

\*The term  $P_m(z)$  is a polynomial of degree  $m$  satisfying  $P_{m+1}(z) = (mz + 1)p_m(z) + z(1 - z)p'_m(z)$ ,  $p_1 = 1$

To solve the linear difference equation  $\sum_{i=0}^k p_i y_{n+k-i} = 0$ ,  $p_0 = 1$  we associate with it the two formal series  $P = p_0 + p_1 x + \cdots + p_k x^k$  and  $Y = y_0 + y_1 x + y_2 x^2 + \cdots$ . If  $p(x)$  is the characteristic polynomial then  $P(x) = x^k p(1/x) = \bar{p}(x)$ . The product of the two series is  $Q = YP = q_0 + q_1 x + \cdots + q_{k-1} x^{k-1} + q_k x^k + \cdots$  where  $q_n = \sum_{i=0}^n p_i y_{n-i}$ . Because  $p_{k+1} = p_{k+2} = \cdots = 0$ , it is obvious that  $q_{k+1} = q_{k+2} = \cdots = 0$ —that is,  $Q$  is a polynomial (formal series with finite number of terms). Then  $Y = P^{-1}Q = q(x)/\bar{p}(x) = q(x)/x^k p(1/x)$ , where  $p$  is the characteristic polynomial and  $q(x) = \sum_{i=0}^k q_i x^i$ . The roots of  $\bar{p}(x)$  are  $x_i^{-1}$  where the  $x_i$  are the roots of  $p(x)$ .

**Theorem 1.** If the roots of  $p(x)$  are less than one in absolute value, then  $Y(x)$  converges for  $|x| < 1$ .

**Theorem 2.** If  $p(x)$  has no roots greater than one in absolute value and those on the unit circle are simple roots, then the coefficients  $y_n$  of  $Y$  are bounded. Now  $q_k = g_0$ ,  $q_{n+k} = g_n$ , and  $Q(x) = Q_1(x) + x^k Q_2(x)$ . Hence  $\sum_{i=1}^{\infty} y_i x^i = [Q_1(x) + x^k Q_2(x)]/\bar{p}(x)$ .

### Example 200.2

Consider the equation  $y_{n+1} + y_n = -(n+1)$ ,  $y_0 = 1$ . Here  $Q_1 = 1$ ,  $Q_2 = -\sum_{n=0}^{\infty} (n+1)x^n = -1/(1-x)^2$ .

$$G(x) = \frac{1 - x/(1-x)^2}{1+x} = \frac{5}{4} \frac{1}{1+x} - \frac{1}{4} \frac{1}{1-x} - \frac{1}{2} \frac{x}{(1-x)^2}.$$

Using the table term by term, we find  $\sum_{n=0}^{\infty} y_n x^n = \sum_{n=0}^{\infty} \left[ \frac{5}{4}(-1)^n - \frac{1}{4} - \frac{1}{2}n \right] x^n$ , so  $y_n = \frac{5}{4}(-1)^n - \frac{1}{4} - \frac{1}{2}n$ .

**201.2 Partial Differential Equations**

Methods of Solution

**William F. Ames***Georgia Institute of Technology*

Any equation involving derivatives is called a *differential equation*. If there is only one independent variable the equation is termed a *total differential equation* or an *ordinary differential equation*. If there is more than one independent variable the equation is called a *partial differential equation*. If the highest-order derivative is the  $n$ th then the equation is said to be  $n$ th order. If there is no function of the dependent variable and its derivatives other than the linear one, the equation is said to be *linear*. Otherwise, it is *nonlinear*. Thus  $(d^3y/dx^3) + a(dy/dx) + by = 0$  is a *linear* third-order ordinary (total) differential equation. If we replace  $by$  with  $by^3$ , the equation becomes nonlinear. An example of a second-order linear partial differential equation is the famous wave equation  $(\partial^2 u / \partial x^2) - a^2(\partial^2 u / \partial t^2) = f(x)$ . There are two independent variables  $x$  and  $t$  and  $a^2 > 0$  (of course). If we replace  $f(x)$  by  $f(u)$  (say  $u^3$  or  $\sin u$ ) the equation is nonlinear. Another example of a nonlinear third-order partial differential equation is  $u_t + uu_x = au_{xxx}$ . This chapter uses the common subscript notation to indicate the partial derivatives.

Now we briefly indicate some methods of solution and the solution of some commonly occurring equations.

---

**201.1 Ordinary Differential Equations**

---

**First-Order Equations**

The *general* first-order equation is  $f(x, y, y') = 0$ . Equations capable of being written in either of the forms  $y' = f(x)g(y)$  or  $f(x)g(y)y' + F(x)G(y) = 0$  are *separable* equations. Their solution is obtained by using  $y' = dy/dx$  and writing the equations in differential form as  $dy/g(y) = f(x)dx$  or  $g(y)[dy/G(y)] = -F(x)[dx/f(x)]$  and integrating. An example is the famous *logistic* equation of inhibited growth  $(dy/dt) = ay(1 - y)$ . The integral of  $dy/y(1 - y) = a dt$  is  $y = 1/[1 + (y_0^{-1} - 1)e^{-at}]$  for  $t \geq 0$  and  $y(0) = y_0$  (the initial state called

the *initial condition*).

Equations may not have unique solutions. An example is  $y' = 2y^{1/2}$  with the initial condition  $y(0) = 0$ . One solution by separation is  $y = x^2$ . But there are an *infinity* of others—namely,  $y_a(x) = 0$  for  $-\infty < x \leq a$ , and  $(x - a)^2$  for  $a \leq x < \infty$ .

If the equation  $P(x, y) dy + Q(x, y) dx$  is reducible to

$$\frac{dy}{dx} = f\left(\frac{y}{x}\right) \quad \text{or} \quad \frac{dy}{dx} = f\left(\frac{a_1x + b_1y + c_1}{a_2x + b_2y + c_2}\right)$$

the equation is called *homogeneous* (nearly homogeneous). The first form reduces to the separable equation  $u + x(du/dx) = f(u)$  with the substitution  $y/x = u$ . The nearly homogeneous equation is handled by setting  $x = X + \alpha$ ,  $y = Y + \beta$ , and choosing **a** and **b** so that  $a_1\alpha + b_1\beta + c_1 = 0$

and  $a_2\alpha + b_2\beta + c_2 = 0$ . If  $\begin{vmatrix} a_1 & b_1 \\ a_2 & b_2 \end{vmatrix} \neq 0$  this is always possible; the equation becomes

$dY/dX = [a_1 + b_1(Y/X)]/[a_2 + b_2(Y/X)]$  and the substitution  $Y = Xu$  gives a separable equation. If  $\begin{vmatrix} a_1 & b_1 \\ a_2 & b_2 \end{vmatrix} = 0$  then  $a_2x + b_2y = k(a_1x + b_1y)$  and the equation becomes

$du/dx = a_1 + b_1(u + c_1)/(ku + c_2)$ , with  $u = a_1x + b_1y$ . Lastly, any equation of the form  $dy/dx = f(ax + by + c)$  transforms into the separable equation  $du/dx = a + bf(u)$  using the change of variable  $u = ax + by + c$ .

The general first-order linear equation is expressible in the form  $y' + f(x)y = g(x)$ . It has the *general solution* (a solution with an arbitrary constant  $c$ )

$$y(x) = \exp\left[-\int f(x) dx\right] \left\{c + \int \exp[f(x) dx]g(x) dx\right\}$$

Two noteworthy examples of first-order equations are as follows:

1. An often-occurring nonlinear equation is the *Bernoulli equation*,  $y' + p(x)y = g(x)y^\alpha$ , with **a** real,  $\alpha \neq 0$ ,  $\alpha \neq 1$ . The transformation  $z = y^{1-\alpha}$  converts the equation to the linear first-order equation  $z' + (1 - \alpha)p(x)z = (1 - \alpha)g(x)$ .
2. The famous *Riccati equation*,  $y' = p(x)y^2 + q(x)y + r(x)$ , cannot in general be solved by integration. But some useful transformations are helpful. The substitution  $y = y_1 + u$  leads to the equation  $u' - (2py_1 + q)u = pu^2$ , which is a Bernoulli equation for  $u$ . The substitution  $y = y_1 + v^{-1}$  leads to the equation  $v' + (2py_1 + q)v + p = 0$ , which is a linear first-order equation for  $v$ . Once either of these equations has been solved, the general solution of the Riccati equation is  $y = y_1 + u$  or  $y = y_1 + v^{-1}$ .

## Second-Order Equations

The simplest of the second-order equations is  $y'' + ay' + by = 0$  ( $a, b$  real), with the initial conditions  $y(x_0) = y_0$ ,  $y'(x_0) = y'_0$  or the boundary conditions  $y(x_0) = y_0$ ,  $y(x_1) = y_1$ . The

general solution of the equation is given as follows.

1.  $a^2 - 4b > 0$ ,  $\lambda_1 = \frac{1}{2}(-a + \sqrt{a^2 - 4b})$ ,  $\lambda_2 = \frac{1}{2}(-a - \sqrt{a^2 - 4b})$   
 $y = c_1 \exp(\lambda_1 x) + c_2 \exp(\lambda_2 x)$
2.  $a^2 - 4b = 0$ ,  $\lambda_1 = \lambda_2 = -\frac{a}{2}$ ,  $y = (c_1 + c_2 x) \exp(\lambda_1 x)$
3.  $a^2 - 4b < 0$ ,  $\lambda_1 = \frac{1}{2}(-a + i\sqrt{4b - a^2})$ ,  $\lambda_2 = \frac{1}{2}(-a - i\sqrt{4b - a^2})$ ,  $i^2 = -1$   
 With  $p = -a/2$  and  $q = \frac{1}{2}\sqrt{4b - a^2}$ ,

$$y = c_1 \exp[(p + iq)x] + c_2 \exp[(p - iq)x] = \exp(px)[A \sin qx + B \cos qx]$$

The initial conditions or boundary conditions are used to evaluate the arbitrary constants  $c_1$  and  $c_2$  (or  $A$  and  $B$ ).

Note that a linear problem with specified data may not have a solution. This is especially serious if numerical methods are employed without serious thought.

For example, consider  $y'' + y = 0$  with the boundary condition  $y(0) = 1$  and  $y(\pi) = 1$ . The general solution is  $y = c_1 \sin x + c_2 \cos x$ . The first condition  $y(0) = 1$  gives  $c_2 = 1$ , and the second condition requires  $y(\pi) = c_1 \sin \pi + \cos \pi$  or " $1 = -1$ " which is a *contradiction*.

**Example 201.1—The Euler Strut.** When a strut of uniform construction is subjected to a compressive load  $P$  it exhibits no transverse displacement until  $P$  exceeds some critical value  $P_1$ . When this load is exceeded, buckling occurs and large deflections are produced as a result of small load changes. Let the rod of length  $\ell$  be placed as shown in Fig. 201.1.

**Figure 201.1**

From the linear theory of elasticity (Timoshenko), the transverse displacement  $y(x)$  satisfies the linear second-order equation  $y'' = -Py/EI$ , where  $E$  is the modulus of elasticity and  $I$  is the moment of inertia of the strut. The boundary conditions are  $y(0) = 0$  and  $y(a) = 0$ . With  $k^2 = P/EI$  the general solution is  $y = c_1 \sin kx + c_2 \cos kx$ . The condition  $y(0) = 0$  gives  $c_2 = 0$ . The second condition gives  $c_1 \sin ka = 0$ . Since  $c_1 = 0$  gives only the trivial solution  $y = 0$  we must have  $\sin ka = 0$ . This occurs for  $ka = n\pi$ ,  $n = 0, 1, 2, \dots$  (these are called *eigenvalues*). The first nontrivial solution occurs for  $n = 1$ —that is,  $k = \pi/a$ —whereupon  $y_1 = c_1 \sin(\pi x/a)$ , with arbitrary  $c_1$ . Since  $P = EI k^2$  the critical compressive load is  $P_1 = EI\pi^2/a^2$ . This is the buckling load. The weakness of the linear theory is its failure to model

the situation when buckling occurs.

**Example 201.234Some Solvable Nonlinear Equations.** Many physical phenomena are modeled using nonlinear second-order equations. Some general cases are given here.

1.  $y'' = f(y)$  , first integral  $(y')^2 = 2 \int f(y) dy + c$  .
2.  $f(x, y', y'')$  . Set  $p = y'$  and obtain a first-order equation  $f(x, p, dp/dx) = 0$  . Use first-order methods.
3.  $f(y, y', y'') = 0$  . Set  $p = y'$  and then  $y'' = p(dp/dy)$  so that a first-order equation  $f[y, p, p(dp/dy)] = 0$  for  $p$  as a function of  $y$  is obtained.
4. The *Riccati transformation*  $du/dx = yu$  leads to the Riccati chain of equations, which linearize by raising the order. Thus,

	Equation in $y$	Equation in $u$
1.	$y' + y^2 = f(x)$	$u'' = f(x)u$
2.	$y'' + 3yy' + y^3 = f(x)$	$u''' = f(x)u$
3.	$y''' + 6y^2y' + 3(y')^2 + 4yy'' = f(x)$	$u^{(iv)} = f(x)u$

This method can be generalized to  $u' = a(x)yu$  or  $u' = a(x)f(u)y$  .

## Second-Order Inhomogeneous Equations

The general solution of  $a_0(x)y'' + a_1(x)y' + a_2(x)y = f(x)$  is  $y = y_H(x) + y_P(x)$  , where  $y_H(x)$  is the general solution of the homogeneous equation (with the right-hand side zero) and  $y_P$  is the particular integral of the equation. Construction of particular integrals can sometimes be done by the *method of undetermined coefficients*. See Table 201.1. This applies only to the linear constant coefficient case in which the function  $f(x)$  is a linear combination of a polynomial, exponentials, sines and cosines, and some products of these functions. This method has as its basis the observation that repeated differentiation of such functions gives rise to similar functions.

**Table 201.1** Method of Undetermined Coefficients—Equation  $L(y) = f(x)$  (Constant Coefficients)

	Terms in $f(x)$	Terms To Be Included in $y_P(x)$
1.	Polynomial of degree $n$	(i) If $L(y)$ contains $y$ , try $y_P = a_0x^n + a_1x^{n-1} + \cdots + a_n$ . (ii) If $L(y)$ does not contain $y$ and lowest-order derivative is $y^{(r)}$ , try $y_P = a_0x^{n+r} + \cdots + a_nx^r$ .
2.	$\sin qx, \cos qx$	(i) $\sin qx$ and/or $\cos qx$ are not in $y_H$ ; $y_P = B \sin qx + C \cos qx$ . (ii) $y_H$ contains terms of form $x^r \sin qx$ and/or $x^r \cos qx$ for $r = 0, 1, \dots, m$ ; include in $y_P$ terms of the form $a_0x^{m+1} \sin qx + a_1x^{m+1} \cos qx$ .
3.	$e^{ax}$	(i) $y_H$ does not contain $e^{ax}$ ; include $Ae^{ax}$ in $y_P$ . (ii) $y_H$ contains $e^{ax}, xe^{ax}, \dots, x^ne^{ax}$ ; include in $y_P$ terms of

4.  $e^{px} \sin qx, e^{px} \cos qx$
- the form  $Ax^{n+1}e^{ax}$ .
- (i)  $y_H$  does not contain these terms; in  $y_P$  include  $Ae^{px} \sin qx + Be^{px} \cos qx$ .
- (ii)  $y_H$  contains  $x^r e^{px} \sin qx$  and/or  $x^r e^{px} \cos qx$ ;  $r = 0, 1, \dots, m$  include in  $y_P$   $Ax^{m+1}e^{px} \sin qx + Bx^{m+1}e^{px} \cos qx$ .
- 

**Example 201.3.** Consider the equation  $y'' + 3y' + 2y = \sin 2x$ . The characteristic equation of the homogeneous equation  $\lambda^2 + 3\lambda + 2 = 0$  has the two roots  $\lambda_1 = -1$  and  $\lambda_2 = -2$ . Consequently,  $y_H = c_1 e^{-x} + c_2 e^{-2x}$ . Since  $\sin 2x$  is not linearly dependent on the exponentials and since  $\sin 2x$  repeats after two differentiations, we assume a particular solution with undetermined coefficients of the form  $y_P(x) = B \sin 2x + C \cos 2x$ . Substituting into the original equation gives  $-(2B + 6C) \sin 2x + (6B - 2C) \cos 2x = \sin 2x$ . Consequently,  $-(2B + 6C) = 1$  and  $6B - 2C = 0$  to satisfy the equation. These two equations in two unknowns have the solution  $B = -\frac{1}{20}$  and  $C = -\frac{3}{20}$ . Hence  $y_P = -\frac{1}{20}(\sin 2x + 3 \cos 2x)$  and  $y = c_1 e^{-x} + c_2 e^{-2x} - \frac{1}{20}(\sin 2x + 3 \cos 2x)$ .

A general method for finding  $y_P(x)$  called *variation of parameters* uses as its starting point  $y_H(x)$ . This method applies to *all* linear differential equations irrespective of whether they have constant coefficients. But it assumes  $y_H(x)$  is known. We illustrate the idea for  $a(x)y'' + b(x)y' + c(x)y = f(x)$ . If the solution of the homogeneous equation is  $y_H(x) = c_1 \phi_1(x) + c_2 \phi_2(x)$ , then vary the parameters  $c_1$  and  $c_2$  to seek  $y_P(x)$  as  $y_P(x) = u_1(x)\phi_1(x) + u_2(x)\phi_2(x)$ . Then  $y'_P = u_1\phi'_1 + u_2\phi'_2 + u'_1\phi_1 + u'_2\phi_2$  and choose  $u'_1\phi_1 + u'_2\phi_2 = 0$ . Calculating  $y''_P$  and setting in the original equation gives  $a(x)u'_1\phi'_1 + a(x)u'_2\phi'_2 = f$ . Solving the last two equations for  $u'_1$  and  $u'_2$  gives  $u'_1 = -\phi_2 f/wa$ ,  $u'_2 = \phi_1 f/wa$ , where  $w = \phi_1\phi'_2 - \phi'_1\phi_2 \neq 0$ . Integrating the general solution gives  $y = c_1\phi_1(x) + c_2\phi_2(x) - \left\{ \int [\phi_2 f(x)]/wa \right\} \phi_1(x) + \left[ \int (\phi_1 f/wa) dx \right] \phi_2(x)$ .

**Example 201.4.** Consider the equations  $y'' - 4y = \sin x/(1 + x^2)$  and  $y_H = c_1 e^{2x} + c_2 e^{-2x}$ . With  $\phi_1 = e^{2x}$  and  $\phi_2 = e^{-2x}$ ,  $w = 4$ , so the general solution is

$$y = c_1 e^{2x} + c_2 e^{-2x} - \frac{e^{-2x}}{4} \int \frac{e^{2x} \sin x}{1 + x^2} dx + \frac{e^{2x}}{4} \int \frac{e^{-2x} \sin x}{1 + x^2} dx$$

The method of variation of parameters can be generalized as described in the references.

Higher-order systems of linear equations with constant coefficients are treated in a similar manner. Details can be found in the references.

## Series Solution

The solution of differential equations can only be obtained in closed form in special cases. For all others, series or approximate or numerical solutions are necessary. In the simplest case, for an initial value problem, the solution can be developed as a Taylor series expansion about the point

where the initial data are specified. The method fails in the *singular case*<sup>3/4</sup> that is, a point where the coefficient of the highest-order derivative is zero. The general method of approach is called the *Frobenius method*.

To understand the nonsingular case consider the equation  $y'' + xy = x^2$  with  $y(2) = 1$  and  $y'(2) = 2$  (an initial value problem). We seek a series solution of the form  $y(x) = a_0 + a_1(x - 2) + a_2(x - 2)^2 + \cdots$ . To proceed, set  $1 = y(2) = a_0$ , which evaluates  $a_0$ . Next,  $y'(x) = a_1 + 2a_2(x - 2) + \cdots$ , so  $2 = y'(2) = a_1$  or  $a_1 = 2$ . Next  $y''(x) = 2a_2 + 6a_3(x - 2) + \cdots$  and from the equation,  $y'' = x^2 - xy$ , so  $y''(2) = 4 - 2y(2) = 4 - 2 = 2$ . Hence  $2 = 2a_2$  or  $a_2 = 1$ . Thus, to third-order  $y(x) = 1 + 2(x - 2) + (x - 2)^2 + R_2(x)$ , where the remainder  $R_2(x) = [(x - 2)^3/3!] y'''(\xi)$ , where  $2 < \xi < x$  can be bounded for each  $x$  by finding the maximum of  $y'''(x) = 2x - y - xy'$ . The third term of the series follows by evaluating  $y'''(2) = 4 - 1 - 2 \cdot 2 = -1$ , so  $6a_3 = -1$  or  $a_3 = -1/6$ .

By now the nonsingular process should be familiar. The algorithm for constructing a series solution about a nonsingular (ordinary) point  $x_0$  of the equation  $P(x)y'' + Q(x)y' + R(x)y = f(x)$  (note that  $P(x_0) \neq 0$ ) is as follows:

1. Substitute into the differential equation the expressions

$$y(x) = \sum_{n=0}^{\infty} a_n(x - x_0)^n, \quad y'(x) = \sum_{n=1}^{\infty} n a_n(x - x_0)^{n-1},$$

$$y''(x) = \sum_{n=2}^{\infty} n(n-1)a_n(x - x_0)^{n-2}$$

2. Expand  $P(x)$ ,  $Q(x)$ ,  $R(x)$ , and  $f(x)$  about the point  $x_0$  in a power series in  $(x - x_0)$  and substitute these series into the equation.
3. Gather all terms involving the same power of  $(x - x_0)$  to arrive at an identity of the form  $\sum_{n=0}^{\infty} A_n(x - x_0)^n \equiv 0$ .
4. Equate to zero each coefficient  $A_n$  of step 3.
5. Use the expressions of step 4 to determine  $a_2, a_3, \dots$  in terms of  $a_0, a_1$  (we need two arbitrary constants) to arrive at the general solution.
6. With the given initial conditions, determine  $a_0$  and  $a_1$ .

If the equation has a regular singular point—that is, a point  $x_0$  at which  $P(x)$  vanishes and a series expansion is sought about that point—a solution is sought of the form  $y(x) = (x - x_0)^r \sum_{n=0}^{\infty} a_n(x - x_0)^n$ ,  $a_0 \neq 0$  and the index  $r$  and coefficients  $a_n$  must be determined from the equation by an algorithm analogous to that already described. The description of this Frobenius method is left for the references.

## 201.2 Partial Differential Equations

The study of partial differential equations is of continuing interest in applications. It is a vast subject, so the focus in this chapter will be on the most commonly occurring equations in the engineering literature—the second-order equations in two variables. Most of these are of the three basic types: elliptic, hyperbolic, and parabolic.

*Elliptic equations* are often called *potential equations* since they occur in potential problems where the potential may be temperature, voltage, and so forth. They also give rise to the steady solutions of parabolic equations. They require boundary conditions for the complete determination of their solution.

*Hyperbolic equations* are often called *wave equations* since they arise in the propagation of waves. For the development of their solutions, initial and boundary conditions are required. In principle they are solvable by the method of characteristics.

*Parabolic equations* are usually called *diffusion equations* because they occur in the transfer (diffusion) of heat and chemicals. These equations require initial conditions (for example, the initial temperature) and boundary conditions for the determination of their solutions.

Partial differential equations (PDEs) of the second order in two independent variables  $(x, y)$  are of the form  $a(x, y)u_{xx} + b(x, y)u_{xy} + c(x, y)u_{yy} = E(x, y, u, u_x, u_y)$ . If  $E = E(x, y)$  the equation is linear; if  $E$  depends also on  $u$ ,  $u_x$ , and  $u_y$ , it is said to be *quasilinear*, and if  $E$  depends only on  $x$ ,  $y$ , and  $u$ , it is *semilinear*. Such equations are classified as follows: If  $b^2 - 4ac$  is less than, equal to, or greater than zero at some point  $(x, y)$ , then the equation is elliptic, parabolic, or hyperbolic, respectively, at that point. A PDE of this form can be transformed into canonical (standard) forms by use of new variables. These standard forms are most useful in analysis and numerical computations.

For hyperbolic equations the standard form is  $u_{\xi\eta} = \phi(u, u_\eta, u_\xi, \eta, \xi)$ , where  $\xi_x/\xi_y = (-b + \sqrt{b^2 - 4ac})/2a$ , and  $\eta_x/\eta_y = (-b - \sqrt{b^2 - 4ac})/2a$ . The right-hand sides of these equations determine the so-called characteristics  $(dy/dx)|_+ = (-b + \sqrt{b^2 - 4ac})/2a$ ,  $(dy/dx)|_- = (-b - \sqrt{b^2 - 4ac})/2a$ .

**Example 201.5.** Consider the equation  $y^2 u_{xx} - x^2 u_{yy} = 0$ .  $\xi_x/\xi_y = -x/y$ ,  $\eta_x/\eta_y = x/y$ , so  $\xi = y^2 - x^2$  and  $\eta = y^2 + x^2$ . In these new variables the equation becomes  $u_{\xi\eta} = (\xi u_\eta - \eta u_\xi)/2(\xi^2 - \eta^2)$ .

For parabolic equations the standard form is  $u_{\xi\xi} = \phi(u, u_\eta, u_\xi, \eta, \xi)$  or  $u_{\eta\eta} = \phi(u, u_\eta, u_\xi, \xi, \eta)$ , depending upon how the variables are defined. In this case  $\xi_x/\xi_y = -b/2a$  if  $a \neq 0$ , and  $\xi_x/\xi_y = -b/2c$  if  $c \neq 0$ . Only  $\mathbf{x}$  must be determined (there is only one characteristic) and  $\mathbf{h}$  can be chosen as any function that is linearly independent of  $\mathbf{x}$ .

**Example 201.6.** Consider the equation  $y^2 u_{xx} - 2xy u_{xy} + x^2 u_{yy} + u_y = 0$ . Clearly,  $b^2 - 4ac = 0$ . Neither  $a$  nor  $c$  is zero so either path can be chosen. With  $\xi_x/\xi_y = -b/2a = x/y$ , there results  $\xi = x^2 + y^2$ . With  $\eta = x$ , the equation becomes  $u_{\eta\eta} = [2(\xi + \eta)u_\xi + u_\eta]/(\xi - \eta^2)$ .

For *elliptic equations* the standard form is  $u_{\alpha\alpha} + u_{\beta\beta} = \phi(u, u_\alpha, u_\beta, \alpha, \beta)$ , where  $\mathbf{x}$  and  $\mathbf{h}$  are determined by solving the  $\mathbf{x}$  and  $\mathbf{h}$  equations of the hyperbolic system (they are complex) and taking  $\alpha = (\eta + \xi)/2$ ,  $\beta = (\eta - \xi)/2i$  ( $i^2 = -1$ ). Since  $\mathbf{x}$  and  $\mathbf{h}$  are complex conjugates, both  $\mathbf{a}$  and  $\mathbf{b}$  are real.

**Example 201.7.** Consider the equation  $y^2 u_{xx} + x^2 u_{yy} = 0$ . Clearly,  $b^2 - 4ac < 0$ , so the equation is elliptic. Then  $\xi_x/\xi_y = -ix/y$ ,  $\eta_x/\eta_y = ix/y$ , so  $\alpha = (\eta + \xi)/2 = y^2$  and  $\beta = (\eta - \xi)/2i = x^2$ . The standard form is  $u_{\alpha\alpha} + u_{\beta\beta} = -(u_\alpha/2\alpha + u_\beta/2\beta)$ .

Figure 1

Figure 2

Figure 3

Figure 4

The mathematical equations used to generate these three-dimensional figures are worth a thousand words. The figures shown illustrate some of the nonlinear ideas of engineering, applied physics, and chemistry. [Figure 1](#) represents a breather soliton surface for the sine-Gordon equation  $w_{uv} = \sin w$  generated by a Backlund transformation. A single-soliton surface for the sine-Gordon equation  $w_{uv} = \sin w$  is illustrated in [Fig. 2](#). [Figure 3](#) represents a single-soliton surface for the Tzitzeica-Dodd-Bullough equation associated with an integrable anisotropic gas dynamics system. [Figure 4](#) represents a single-soliton Bianchi surface.

The solutions to the equations were developed by W. K. Schief and C. Rogers at the Center for Dynamical Systems and Nonlinear Studies at the Georgia Institute of Technology and the University of New South Wales in Sydney, Australia. All of these three-dimensional projections were generated using the MAPLE software package. (Figures courtesy of Schief and Rogers.)

## Methods of Solution

### Separation of Variables

Perhaps the most elementary method for solving linear PDEs with homogeneous boundary conditions is the method of *separation of variables*. To illustrate, consider  $u_t - u_{xx} = 0$ ,  $u(x, 0) = f(x)$  (the initial condition) and  $u(0, t) = u(1, t) = 0$  for  $t > 0$  (the boundary conditions). A solution is assumed in "separated form"  $u(x, t) = X(x)T(t)$ . Upon substituting into the equation we find  $\dot{T}/T = X''/X$  (where  $\dot{T} = dT/dt$  and  $X'' = d^2X/dx^2$ ). Since  $T = T(t)$  and  $X = X(x)$ , the ratio must be constant, and for finiteness in  $t$  the constant must be negative, say  $-\lambda^2$ . The solutions of the separated equations  $X'' + \lambda^2 X = 0$  with the boundary conditions  $X(0) = 0$ ,  $X(1) = 0$ , and  $\dot{T} = -\lambda^2 T$  are  $X = A \sin \lambda x + B \cos \lambda x$  and  $T = C e^{-\lambda^2 t}$ , where  $A$ ,  $B$ , and  $C$  are arbitrary constants. To satisfy the boundary condition  $X(0) = 0$ ,  $B = 0$ . An infinite number of values of  $\lambda$  (eigenvalues), say  $\lambda_n = n\pi$  ( $n = 1, 2, 3, \dots$ ), permit all the eigenfunctions  $X_n = b_n \sin \lambda_n x$  to satisfy the other boundary condition  $X(1) = 0$ . The solution of the equation and boundary conditions (not the initial condition) is, by superposition,  $u(x, t) = \sum_{n=1}^{\infty} b_n e^{-n^2 \pi^2 t} \sin n\pi x$  (a Fourier sine series), where the  $b_n$  are arbitrary. These values are obtained from the initial condition using the orthogonality properties of the trigonometric function (e.g.,  $\int_{-\pi}^{\pi} \sin mx \sin nx dx$  is 0 for  $m \neq n$  and is  $\pi$  for  $m = n \neq 0$ ) to be  $b_n = 2 \int_0^1 f(r) \sin n\pi r dr$ . Then the solution of the problem is  $u(x, t) = \sum_{n=1}^{\infty} [2 \int_0^1 f(r) \sin n\pi r dr] e^{-n^2 \pi^2 t} \sin n\pi x$ , which is a Fourier sine series.

If  $f(x)$  is a piecewise smooth or a piecewise continuous function defined for  $a \leq x \leq b$ , then its Fourier series within  $a \leq x \leq b$  as its fundamental interval (it is extended periodically outside that interval) is

$$f(x) \sim \frac{1}{2} a_0 + \sum_{n=1}^{\infty} a_n \cos [2n\pi x / (b - a)] + b_n \sin [2n\pi x / (b - a)]$$

where

$$a_n = \left[ \frac{2}{(b-a)} \right] \int_a^b f(x) \cos[2n\pi x/(b-a)] dx, \quad n = 0, 1, \dots$$

$$b_n = \left[ \frac{2}{(b-a)} \right] \int_a^b f(x) \sin[2n\pi x/(b-a)] dx \quad n = 1, 2, \dots$$

The Fourier sine series has  $a_n \equiv 0$ , and the Fourier cosine series has  $b_n \equiv 0$ . The symbol  $\sim$  means that the series converges to  $f(x)$  at points of continuity, and at the (allowable) points of finite discontinuity the series converges to the *average value* of the discontinuous values.

**Caution:** This method *only* applies to linear equations with homogeneous boundary conditions. Linear equations with variable coefficients use other orthogonal functions, such as the Bessel functions, Laguerre functions, Chebyshev functions, and so forth.

Some inhomogeneous boundary value problems can be transformed into homogeneous ones. Consider the problem  $u_t - u_{xx} = 0$ ,  $0 \leq x \leq 1$ ,  $0 \leq t < \infty$  with initial condition  $u(x, 0) = f(x)$ , and boundary conditions  $u(0, t) = g(t)$ ,  $u(1, t) = h(t)$ . To homogenize the boundary conditions set  $u(x, t) = w(x, t) + x[h(t) - g(t)] + g(t)$  and then solve  $w_t - w_{xx} = [\dot{g}(t) - \dot{h}(t)]x - \dot{g}(t)$  with the initial condition  $w(x, 0) = f(x) - x[h(0) - g(0)] + g(0)$  and  $w(0, t) = w(1, t) = 0$ .

## Operational Methods

A number of integral transforms are useful for solving a variety of linear problems. To apply the Laplace transform to the problem  $u_t - u_{xx} = \delta(x)\delta(t)$ ,  $-\infty < x < \infty$ ,  $0 \leq t$  with the initial condition  $u(x, 0^-) = 0$ , where  $\delta$  is the Dirac delta function, we multiply by  $e^{-st}$  and integrate with respect to  $t$  from 0 to  $\infty$ . With the Laplace transform of  $u(x, t)$  denoted by  $U(x, s)$ —that is,  $U(x, s) = \int_0^\infty e^{-st} u(x, t) dt$ —we have  $sU - U_{xx} = \delta(x)$ , which has the solution

$$U(x, s) = A(s)e^{-x\sqrt{s}} + B(s)e^{x\sqrt{s}} \quad \text{for } x > 0$$

$$U(x, s) = C(s)e^{-x\sqrt{s}} + D(s)e^{x\sqrt{s}} \quad \text{for } x < 0$$

Clearly,  $B(s) = C(s) = 0$  for bounded solutions as  $|x| \rightarrow \infty$ . Then, from the boundary condition,  $U(0^+, s) - U(0^-, s) = 0$  and integration of  $sU - U_{xx} = \delta(x)$  from  $0^-$  to  $0^+$  gives  $U_x(0^+, s) - U_x(0^-, s) = -1$ , so  $A = D = 1/2\sqrt{s}$ . Hence,  $U(x, s) = (1/2\sqrt{s})e^{-\sqrt{s}|x|}$  and the inverse is  $u(x, t) = (1/2\pi i) \int_\Gamma e^{st} U(x, s) ds$ , where  $\Gamma$  is a Bromwich path, a vertical line taken to the right of all singularities of  $U$  on the sphere.

## Similarity (Invariance)

This very useful approach is related to dimensional analysis; both have their foundations in group theory. The three important transformations that play a basic role in Newtonian mechanics are translation, scaling, and rotations. Using two independent variables  $x$  and  $t$  and one dependent variable  $u = u(x, t)$ , the *translation group* is  $\bar{x} = x + \alpha a$ ,  $\bar{t} = t + \beta a$ ,  $\bar{u} = u + \gamma a$ ; the *scaling*

group is  $\bar{x} = a^\alpha x$ ,  $\bar{t} = a^\beta t$ , and  $\bar{u} = a^\gamma u$ ; the *rotation group* is  $\bar{x} = x \cos a + t \sin a$ ,  $\bar{t} = t \cos a - x \sin a$ ,  $\bar{u} = u$ , with a nonnegative real number  $a$ . Important in what follows are the *invariants* of these groups. For the translation group there are two  $\eta = x - \lambda t$ ,  $\lambda = \alpha/\beta$ ,  $f(\eta) = u - \varepsilon t$ ,  $\varepsilon = \gamma/\beta$  or  $f(\eta) = u - \theta x$ ,  $\theta = \gamma/\alpha$ ; for the scaling group the invariants are  $\eta = x/t^{\alpha/\beta}$  (or  $t/x^{\beta/\alpha}$ ) and  $f(\eta) = u/t^{\gamma/\beta}$  (or  $u/x^{\gamma/\alpha}$ ); for the rotation group the invariants are  $\eta = x^2 + t^2$  and  $u = f(\eta) = f(x^2 + t^2)$ .

If a PDE and its data (initial and boundary conditions) are left invariant by a transformation group, then similar (invariant) solutions are sought using the invariants. For example, if an equation is left invariant under scaling, then solutions are sought of the form  $u(x, t) = t^{\gamma/\beta} f(\eta)$ ,  $\eta = xt^{-\alpha/\beta}$  or  $u(x, t) = x^{\gamma/\alpha} f(tx^{-\beta/\alpha})$ ; invariance under translation gives solutions of the form  $u(x, t) = f(x - \lambda t)$ ; and invariance under rotation gives rise to solutions of the form  $u(x, t) = f(x^2 + t^2)$ .

Examples of invariance include the following:

1. The equation  $u_{xx} + u_{yy} = 0$  is invariant under rotation, so we search for solutions of the form  $u = f(x^2 + y^2)$ . Substitution gives the ODE  $f' + \eta f'' = 0$  or  $(\eta f')' = 0$ . The solution is  $u(x, t) = c \ln \eta = c \ln(x^2 + t^2)$ , which is the (so-called) fundamental solution of Laplace's equation.
2. The nonlinear diffusion equation  $u_t = (u^n u_x)_x$  ( $n > 0$ ),  $0 \leq x$ ,  $0 \leq t$ ,  $u(0, t) = ct^n$  is invariant under scaling with the similar form  $u(x, t) = t^n f(\eta)$ ,  $\eta = xt^{-(n+1)/2}$ . Substituting into the PDE gives the equation  $(f^n f')' + ((n+1)/2)\eta f' - nf = 0$ , with  $f(0) = c$  and  $f(\infty) = 0$ . Note that the equation is an ODE.
3. The wave equation  $u_{xx} - u_{tt} = 0$  is invariant under translation. Hence, solutions exist of the form  $u = f(x - \lambda t)$ . Substitution gives  $f''(1 - \lambda^2) = 0$ . Hence,  $\lambda = \pm 1$  or  $f$  is linear. Rejecting the trivial linear solution we see that  $u = f(x - t) + g(x + t)$ , which is the general (d'Alembert) solution of the wave equation; the quantities  $x - t = \alpha$ ,  $x + t = \beta$  are the characteristics of the next section.

The construction of all transformations that leave a PDE invariant is a solved problem left for the references.

The study of "solitons" (solitary traveling waves with special properties) has benefited from symmetry considerations. For example, the nonlinear third-order (Korteweg–de Vries) equation  $u_t + uu_x - au_{xxx} = 0$  is invariant under translation. Solutions are sought of the form  $u = f(x - \lambda t)$ , and  $f$  satisfies the ODE, in  $\eta = x - \lambda t$ ,  $-\lambda f' + ff' - af''' = 0$ .

## Characteristics

Using the characteristics of the solution of the hyperbolic problem  $u_{tt} - u_{xx} = p(x, t)$ ,  $-\infty < x < \infty$ ,  $0 \leq t$ ,  $u(x, 0) = f(x)$ ,  $u_t(x, 0) = h(x)$  is

$$u(x, t) = \frac{1}{2} \int_0^t d\tau \int_{x-(t-\tau)}^{x+(t-\tau)} p(\xi, \tau) d\xi + \frac{1}{2} \int_{x-t}^{x+t} h(\xi) d\xi + \frac{1}{2}[f(x+t) + f(x-t)]$$

The solution of  $u_{tt} - u_{xx} = 0$ ,  $0 \leq x < \infty$ ,  $0 \leq t < \infty$ ,  $u(x, 0) = 0$ ,  $u_t(x, 0) = h(x)$ ,

$u(0, t) = 0$  ,  $t > 0$  is  $u(x, t) = \frac{1}{2} \int_{-x+t}^{x+t} h(\xi) d\xi$  .

The solution of  $u_{tt} - u_{xx} = 0$  ,  $0 \leq x < \infty$  ,  $0 \leq t < \infty$  ,  $u(x, 0) = 0$  ,  $u_t(x, 0) = 0$  ,  $u(0, t) = g(t)$  ,  $t > 0$  is

$$u(x, t) = \begin{cases} 0 & \text{if } t < x \\ g(t - x) & \text{if } t > x \end{cases}$$

From time to time, lower-order derivatives appear in the PDE in use. To remove these from the equation  $u_{tt} - u_{xx} + au_x + bu_t + cu = 0$  , where  $a$ ,  $b$ , and  $c$  are constants, set  $\xi = x + t$  ,

$\mu = t - x$  , whereupon  $u(x, t) = u[(\xi - \mu)/2, (\xi + \mu)/2] = U(\xi, \mu)$  , where

$U_{\xi\mu} + [(b + a)/4]U_{\xi} + [(b - a)/4]U_{\mu} + (c/4)U = 0$  . The transformation

$U(\xi, \mu) = W(\xi, \mu) \exp[-(b - a)\xi/4 - (b + a)\mu/4]$  reduces to satisfying  $W_{\xi\mu} + \lambda W = 0$  , where  $\lambda = (a^2 - b^2 + 4c)/16$  . If  $\lambda \neq 0$  , we lose the simple d'Alembert solution. But the equation for  $W$  is still easier to handle.

In linear problems discontinuities propagate along characteristics. In nonlinear problems the situation is usually different. The characteristics are often used as new coordinates in the numerical method of characteristics.

## Green's Function

Consider the diffusion problem  $u_t - u_{xx} = \delta(t) \delta(x - \xi)$  ,  $0 \leq x < \infty$  ,  $\xi > 0$  ,  $u(0, t) = 0$  ,

$u(x, 0) = 0$  [ $u(\infty, t) = u(\infty, 0) = 0$ ] , a problem that results from a unit source somewhere in the domain subject to a homogeneous (zero) boundary condition. The solution is called a *Green's function of the first kind*. For this problem there is  $G_1(x, \xi, t) = F(x - \xi, t) - F(x + \xi, t)$  , where  $F(x, t) = e^{-x^2/4t} / \sqrt{4\pi t}$  is the *fundamental* (invariant) *solution*. More generally, the solution of  $u_t - u_{xx} = \delta(x - \xi) \delta(t - \tau)$  ,  $\xi > 0$  ,  $\tau > 0$  , with the same conditions as before, is the Green's function of the first kind

$$G_1(x, \xi, t - \tau) = \frac{1}{\sqrt{4\pi(t - \tau)}} \left[ e^{-(x-\xi)^2/4(t-\tau)} - e^{-(x+\xi)^2/4(t-\tau)} \right]$$

for the semiinfinite interval.

The solution of  $u_t - u_{xx} = p(x, t)$  ,  $0 \leq x < \infty$  ,  $0 \leq t < \infty$  , with  $u(x, 0) = 0$  ,  $u(0, t) = 0$  ,  $t > 0$  is  $u(x, t) = \int_0^t d\tau \int_0^\infty p(\xi, \tau) G_1(x, \xi, t - \tau) d\xi$  , which is a superposition. Note that the Green's function and the desired solution must both satisfy a zero boundary condition at the origin for this solution to make sense.

The solution of  $u_t - u_{xx} = 0$  ,  $0 \leq x < \infty$  ,  $0 \leq t < \infty$  ,  $u(x, 0) = f(x)$  ,  $u(0, t) = 0$  ,  $t > 0$  is  $u(x, t) = \int_0^\infty f(\xi) G_1(x, \xi, t) d\xi$  .

The solution of  $u_t - u_{xx} = 0$  ,  $0 \leq x < \infty$  ,  $0 \leq t < \infty$  ,  $u(x, 0) = 0$  ,  $u(0, t) = g(t)$  ,  $t > 0$  (nonhomogeneous) is obtained by transforming to a new problem that has a homogeneous boundary condition. Thus, with  $w(x, t) = u(x, t) - g(t)$  the equation for  $w$  becomes

$w_t - w_{xx} = -\dot{g}(t) - g(0) \delta(t)$  and  $w(x, 0) = 0$  ,  $w(0, t) = 0$  . Using  $G_1$  , above, we finally obtain  $u(x, t) = (x/\sqrt{4\pi}) \int_0^t g(t - \tau) e^{-x^2/4t} / \tau^{3/2} d\tau$  .

The Green's function approach can also be employed for elliptic and hyperbolic problems.

### Equations in Other Spatial Variables

The spherically symmetric wave equation  $u_{rr} + 2u_r/r - u_{tt} = 0$  has the general solution

$$u(r, t) = [f(t - r) + g(t + r)]/r \quad .$$

The Poisson-Euler-Darboux equation, arising in gas dynamics,

$$u_{rs} + N(u_r + u_s)/(r + s) = 0$$

where  $N$  is a positive integer  $\geq 1$ , has the general solution

$$u(r, s) = k + \frac{\partial^{N-1}}{\partial r^{N-1}} \left[ \frac{f(r)}{(r + s)^N} \right] + \frac{\partial^{N-1}}{\partial s^{N-1}} \left[ \frac{g(s)}{(r + s)^N} \right]$$

Here,  $k$  is an arbitrary constant and  $f$  and  $g$  are arbitrary functions whose form is determined from the problem initial and boundary conditions.

### Conversion to Other Orthogonal Coordinate Systems

Let  $(x^1, x^2, x^3)$  be rectangular (Cartesian) coordinates and  $(u^1, u^2, u^3)$  be any orthogonal coordinate system related to the rectangular coordinates by  $x^i = x^i(u^1, u^2, u^3)$ ,  $i = 1, 2, 3$ . With  $(ds)^2 = (dx^1)^2 + (dx^2)^2 + (dx^3)^2 = g_{11}(du^1)^2 + g_{22}(du^2)^2 + g_{33}(du^3)^2$ , where  $g_{ii} = (\partial x^1 / \partial u^i)^2 + (\partial x^2 / \partial u^i)^2 + (\partial x^3 / \partial u^i)^2$ . In terms of these "metric" coefficients the basic operations of applied mathematics are expressible. Thus (with  $g = g_{11} g_{22} g_{33}$ )

$$dA = (g_{11} g_{22})^{1/2} du^1 du^2; \quad dV = (g_{11} g_{22} g_{33})^{1/2} du^1 du^2 du^3;$$

$$\text{grad } \phi = \frac{\vec{a}_1}{(g_{11})^{1/2}} \frac{\partial \phi}{\partial u^1} + \frac{\vec{a}_2}{(g_{22})^{1/2}} \frac{\partial \phi}{\partial u^2} + \frac{\vec{a}_3}{(g_{33})^{1/2}} \frac{\partial \phi}{\partial u^3}$$

( $\vec{a}_i$  are unit vectors in direction  $i$ );

$$\text{div } \vec{E} = g^{-1/2} \left\{ \frac{\partial}{\partial u^1} [(g_{22} g_{33})^{1/2} E_1] + \frac{\partial}{\partial u^2} [(g_{11} g_{33})^{1/2} E_2] + \frac{\partial}{\partial u^3} [(g_{11} g_{22})^{1/2} E_3] \right\}$$

[here  $\vec{E} = (E_1, E_2, E_3)$ ];

$$\begin{aligned} \text{curl } \vec{E} = g^{-1/2} \left\{ \vec{a}_1 (g_{11})^{1/2} \left( \frac{\partial}{\partial u^2} [(g_{33})^{1/2} E_3] - \frac{\partial}{\partial u^3} [(g_{22})^{1/2} E_2] \right) \right. \\ + \vec{a}_2 (g_{22})^{1/2} \left( \frac{\partial}{\partial u^3} [(g_{11})^{1/2} E_1] - \frac{\partial}{\partial u^1} [(g_{33})^{1/2} E_3] \right) \\ \left. + \vec{a}_3 (g_{33})^{1/2} \left( \frac{\partial}{\partial u^1} [(g_{22})^{1/2} E_2] - \frac{\partial}{\partial u^2} [(g_{11})^{1/2} E_1] \right) \right\} \end{aligned}$$

$$\text{div grad } \psi = \nabla^2 \psi = \text{Laplacian of } \psi = g^{-1/2} \sum_{i=1}^3 \frac{\partial}{\partial u^i} \left[ \frac{g^{1/2}}{g_{ii}} \frac{\partial \psi}{\partial u^i} \right]$$

Table 201.2 shows some coordinate systems.

**Table 201.2** Some Coordinate Systems

Coordinate System	Metric Coefficients	
Circular Cylindrical		
$x = r \cos \theta$	$u^1 = r$	$g_{11} = 1$
$y = r \sin \theta$	$u^2 = \theta$	$g_{22} = r^2$
$z = z$	$u^3 = z$	$g_{33} = 1$
Spherical		
$x = r \sin \psi \cos \theta$	$u^1 = r$	$g_{11} = 1$
$y = r \sin \psi \sin \theta$	$u^2 = \psi$	$g_{22} = r^2$
$z = r \cos \theta$	$u^3 = \theta$	$g_{33} = r^2 \sin^2 \psi$
Parabolic Coordinates		
$x = \mu \nu \cos \theta$	$u^1 = \mu$	$g_{11} = \mu^2 + \nu^2$
$y = \mu \nu \sin \theta$	$u^2 = \nu$	$g_{22} = \mu^2 + \nu^2$
$z = \frac{1}{2}(\mu^2 - \nu^2)$	$u^3 = \theta$	$g_{33} = \mu^2 \nu^2$

Other metric coefficients and so forth can be found in Moon and Spencer [1961].

[202.1 Classification and Notation](#)[202.2 Relation to Differential Equations](#)[202.3 Methods of Solution](#)

Convolution Equations • Abel Equation • Approximate Method (Picard's Method)

**William F. Ames**

Georgia Institute of Technology

---

**202.1 Classification and Notation**

---

Any equation in which the unknown function  $u(x)$  appears under the integral sign is called an *integral equation*. If  $f(x)$ ,  $K(x, t)$ ,  $a$ , and  $b$  are known then the integral equation for  $u$ ,  $\int_a^b K(x, t)u(t) dt = f(x)$  is called a *linear integral equation of the first kind of Fredholm type*.  $K(x, t)$  is called the *kernel function* of the equation. If  $b$  is replaced by  $x$  (the independent variable) the equation is an equation of *Volterra type of the first kind*.

An equation of the form  $u(x) = f(x) + \lambda \int_a^b K(x, t)u(t) dt$  is said to be a linear integral equation of *Fredholm type of the second kind*. If  $b$  is replaced by  $x$  it is of *Volterra type*. If  $f(x)$  is not present the equation is homogeneous.

The equation  $\phi(x)u(x) = f(x) + \lambda \int_a^b \text{or } x K(x, t)u(t) dt$  is the *third kind equation* of Fredholm or Volterra type. If the unknown function  $u$  appears in the equation in any way other than to the first power then the integral equation is said to be *nonlinear*. Thus,  $u(x) = f(x) + \int_a^b K(x, t) \sin u(t) dt$  is nonlinear. An integral equation is said to be *singular* when either or both of the limits of integration are infinite or if  $K(x, t)$  becomes infinite at one or more points of the integration interval.

**Example 202.1.** Consider the singular equations  $u(x) = x + \int_0^\infty \sin(xt)u(t) dt$  and  $f(x) = \int_0^x [u(t)/(x-t)^2] dt$ .

---

**202.2 Relation to Differential Equations**

---

The *Leibnitz rule*

$$(d/dx) \int_{a(x)}^{b(x)} F(x, t) dt = \int_{a(x)}^{b(x)} (\partial F / \partial x) dt + F[x, b(x)](db/dx) - F[x, a(x)](da/dx)$$
 is useful

for differentiation of an integral involving a parameter ( $x$  in this case). With this, one can establish the relation

$$I_n(x) = \int_a^x (x-t)^{n-1} f(t) dt = (n-1)! \underbrace{\int_a^x \cdots \int_a^x}_{n \text{ times}} f(x) \underbrace{dx \cdots dx}_{n \text{ times}}$$

This result will be used to establish the relation of the second-order initial value problem to a Volterra integral equation.

The second-order differential equation  $y''(x) + A(x)y'(x) + B(x)y = f(x)$  ,  $y(a) = y_0$  ,  $y'(a) = y'_0$  is equivalent to the integral equations

$$\begin{aligned} y(x) = & - \int_a^x \{A(t) + (x-t)[B(t) - A'(t)]\} y(t) dt \\ & + \int_a^x (x-t)f(t) dt + [A(a)y_0 + y'_0](x-a) + y_0 \end{aligned}$$

which is of the type  $y(x) = \int_a^x K(x,t)y(t) dt + F(x)$  , where

$K(x,t) = (t-x)[B(t) - A'(t)] - A(t)$  and  $F(x)$  includes the rest of the terms. Thus, this initial value problem is equivalent to a Volterra integral equation of the second kind.

**Example 202.2.** Consider the equation  $y'' + x^2y' + xy = x$  ,  $y(0) = 1$  ,  $y'(0) = 0$  . Here  $A(x) = x^2$  ,  $B(x) = x$  ,  $f(x) = x$  ,  $a = 0$  ,  $y_0 = 1$  ,  $y'_0 = 0$  . The integral equation is  $y(x) = \int_0^x t(x-2t)y(t) dt + (x^3/6) + 1$  .

The expression for  $I_n(x)$  can also be useful in converting boundary value problems to integral equations. For example, the problem  $y''(x) + \lambda y = 0$  ,  $y(0) = 0$  ,  $y(a) = 0$  is equivalent to the Fredholm equation  $y(x) = \lambda \int_0^a K(x,t)y(t) dt$  , where  $K(x,t) = (t/a)(a-x)$  when  $t < x$  and  $K(x,t) = (x/a)(a-t)$  when  $t > x$  .

In both cases the differential equation can be recovered from the integral equation by using the Leibnitz rule.

Nonlinear differential equations can also be transformed into integral equations. In fact this is one method used to establish properties of the equation and to develop approximate and numerical solutions. For example, the "forced pendulum" equation  $y''(x) + a^2 \sin y(x) = f(x)$  ,  $y(0) = y(1) = 0$  transforms into the nonlinear Fredholm equation

$$y(x) = \int_0^1 K(x,t)[a^2 \sin y(t) - f(t)] dt$$

with  $K(x,t) = x(1-y)$  for  $0 < x < t$  and  $K(x,t) = t(1-x)$  for  $t < x < 1$  .

## 202.3 Methods of Solution

---

Only the simplest integral equations can be solved exactly. Usually approximate or numerical methods are employed. The advantage here is that integration is a "smoothing operation," whereas differentiation is a "roughening operation." A few exact and approximate methods are given in the following sections. The numerical methods are found in **Chapter 209**.

### Convolution Equations

The special convolution equation  $y(x) = f(x) + \lambda \int_0^x K(x-t)y(t) dt$  is a special case of the Volterra equation of the second kind.  $K(x-t)$  is said to be a *convolution kernel*. The integral part is the convolution integral discussed in **Chapter 204**. The solution can be accomplished by transforming with the Laplace transform:  $L[y(x)] = L[f(x)] + \lambda L[y(x)]L[K(x)]$  or  $y(x) = L^{-1}\{L[f(x)]/(1 - \lambda L[K(x)])\}$ .

### Abel Equation

The Volterra equation  $f(x) = \int_0^x y(t)/(x-t)^\alpha dt$ ,  $0 < \alpha < 1$  is the (singular) Abel equation. Its solution is  $y(x) = (\sin \alpha\pi/\pi)(d/dx) \int_0^x F(t)/(x-t)^{1-\alpha} dt$ .

### Approximate Method (Picard's Method)

This method is one of successive approximations that is described for the equation  $y(x) = f(x) + \lambda \int_a^x K(x,t)y(t) dt$ . Beginning with an initial guess  $y_0(t)$  (often the value at the initial point  $a$ ) generate the next approximation with  $y_1(x) = f(x) + \lambda \int_a^x K(x,t)y_0(t) dt$  and continue with the general iteration

$$y_n(x) = f(x) + \lambda \int_a^x K(x,t)y_{n-1}(t) dt$$

Then, by iterating, one studies the convergence of this process, as is described in the literature.

**Example 202.3.** Let  $y(x) = 1 + \int_0^x xt[y(t)]^2 dt$ ,  $y(0) = 1$ . With  $y_0(t) = 1$  we find  $y_1(x) = 1 + \int_0^x xt dt = 1 + (x^3/2)$  and  $y_2(x) = 1 + \int_0^x xt[1 + (t^3/2)]^2 dt$ , and so forth.

**203.1 Perturbation**

Regular Perturbation • Singular Perturbation • Boundary Layer Method

**203.2 Iterative Methods**

Taylor Series • Picard's Method

**William F. Ames***Georgia Institute of Technology*

The term *approximation methods* usually refers to an analytical process that generates a symbolic approximation rather than a numerical one. Thus,  $1 + x + x^2/2$  is an approximation of  $e^x$  for small  $x$ . This chapter introduces some techniques for approximating the solution of various operator equations.

**203.1 Perturbation****Regular Perturbation**

This procedure is applicable to *some* equations in which a small parameter,  $\varepsilon$ , appears. Use this procedure with care; the procedure involves expansion of the dependent variables and data in a power series in the small parameter. The following example illustrates the procedure.

**Example 203.1.** Consider the equation  $y'' + \varepsilon y' + y = 0$ ,  $y(0) = 1$ ,  $y'(0) = 0$ . Write  $y(x; \varepsilon) = y_0(x) + \varepsilon y_1(x) + \varepsilon^2 y_2(x) + \cdots$ , and the initial conditions (data) become

$$\begin{aligned} y_0(0) + \varepsilon y_1(0) + \varepsilon^2 y_2(0) + \cdots &= 1 \\ y'_0(0) + \varepsilon y'_1(0) + \varepsilon^2 y'_2(0) + \cdots &= 0 \end{aligned}$$

Equating like powers of  $\varepsilon$  in all three equations yields the sequence of equations

$$\begin{aligned} O(\varepsilon^0) : \quad y''_0 + y_0 &= 0, & y_0(0) &= 1, & y'_0(0) &= 0 \\ O(\varepsilon^1) : \quad y''_1 + y_1 &= -y'_0, & y_1(0) &= 0, & y'_1(0) &= 0 \\ & \vdots \end{aligned}$$

The solution for  $y_0$  is  $y_0 = \cos x$  and using this for  $y_1$  we find  $y_1(x) = \frac{1}{2}(\sin x - x \cos x)$ . So  $y(x; \varepsilon) = \cos x + \varepsilon(\sin x - x \cos x)/2 + O(\varepsilon^2)$ . Appearance of the term  $x \cos x$  indicates a *secular term* that becomes arbitrarily large as  $x \rightarrow \infty$ . Hence, this approximation is valid only for  $x \ll 1/\varepsilon$  and for small  $\varepsilon$ . If an approximation is desired over a larger range of  $x$  then the method of multiple scales is required.

## Singular Perturbation

The *method of multiple scales* is a singular method that is *sometimes* useful if the regular perturbation method fails. In this case the assumption is made that the solution depends on *two* (or more) different length (or time) scales. By trying various possibilities, one can determine those scales. The scales are treated as dependent variables when transforming the given ordinary differential equation into a partial differential equation, but then the scales are treated as independent variables when solving the equations.

**Example 203.2.** Consider the equation  $\varepsilon y'' + y' = 2$ ,  $y(0) = 0$ ,  $y(1) = 1$ . This is singular since (with  $\varepsilon = 0$ ) the resulting first-order equation cannot satisfy both boundary conditions. For the problem the proper length scales are  $u = x$  and  $v = x/\varepsilon$ . The second scale can be ascertained by substituting  $\varepsilon^n x$  for  $x$  and requiring  $\varepsilon y''$  and  $y'$  to be of the same order in the transformed equation. Then

$$\frac{d}{dx} = \frac{\partial}{\partial u} \frac{du}{dx} + \frac{\partial}{\partial v} \frac{dv}{dx} = \frac{\partial}{\partial u} + \frac{1}{\varepsilon} \frac{\partial}{\partial v}$$

and the equation becomes

$$\varepsilon \left( \frac{\partial}{\partial u} + \frac{1}{\varepsilon} \frac{\partial}{\partial v} \right)^2 y + \left( \frac{\partial}{\partial u} + \frac{1}{\varepsilon} \frac{\partial}{\partial v} \right) y = 2.$$

With  $y(x; \varepsilon) = y_0(u, v) + \varepsilon y_1(u, v) + \varepsilon^2 y_2(u, v) + \cdots$  we have terms

$$O(\varepsilon^{-1}) : \frac{\partial^2 y_0}{\partial v^2} + \frac{\partial y_0}{\partial v} = 0 \quad (\text{actually ODEs with parameter } u)$$

$$O(\varepsilon^0) : \frac{\partial^2 y_1}{\partial v^2} + \frac{\partial y_1}{\partial v} = 2 - 2 \frac{\partial^2 y_0}{\partial u \partial v} - \frac{\partial y_0}{\partial u}$$

$$O(\varepsilon^1) : \frac{\partial^2 y_2}{\partial v^2} + \frac{\partial y_2}{\partial v} = -2 \frac{\partial^2 y_1}{\partial u \partial v} - \frac{\partial y_1}{\partial u} - \frac{\partial^2 y_0}{\partial u^2}$$

$\vdots$

Then  $y_0(u, v) = A(u) + B(u)e^{-v}$  and so the second equation becomes

$\partial^2 y_1 / \partial v^2 + \partial y_1 / \partial v = 2 - A'(u) + B'(u)e^{-v}$  , with the solution  
 $y_1(u, v) = [2 - A'(u)]v + vB'(u)e^{-v} + D(u) + E(u)e^{-v}$  . Here  $A, B, D$  and  $E$  are still arbitrary.  
 Now the solvability condition—"higher order terms must vanish no slower (as  $\varepsilon \rightarrow 0$ ) than the previous term" [[Kevorkian and Cole, 1981](#)]  
 is used. For  $y_1$  to vanish no slower than  $y_0$  we must have  $2 - A'(u) = 0$  and  $B'(u) = 0$  . If this were not true the terms in  $y_1$  would be larger than those in  $y_0$  ( $v \gg 1$ ) . Thus  $y_0(u, v) = (2u + A_0) + B_0 e^{-v}$  , or in the original variables  
 $y(x; \varepsilon) \approx (2x + A_0) + B_0 e^{-x/\varepsilon}$  and matching to both boundary conditions gives  
 $y(x; \varepsilon) \approx 2x - (1 - e^{-x/\varepsilon})$  .

## Boundary Layer Method

The boundary layer method is applicable to regions in which the solution is *rapidly varying*. See the references at the end of the chapter for detailed discussion.

## 203.2 Iterative Methods

---

### Taylor Series

If it is known that the solution of a differential equation has a power series in the independent variable ( $t$ ), then we may proceed from the initial data (the easiest problem) to compute the Taylor series by differentiation.

**Example 203.3.** Consider the equation  $(d^2 x / dt^2) = -x - x^2$  ,  $x(0) = 1$  ,  $x'(0) = 1$  . From the differential equation,  $x''(0) = -2$  , and, since  $x''' = -x' - 2xx'$  ,  $x'''(0) = -1 - 2 = -3$  , so the four term approximation for  $x(t) \approx 1 + t - (2t^2/2!) - (3t^3/3!) = 1 + t - t^2 - t^3/2$  . An estimate for the error at  $t = t_1$  , (see a discussion of series methods in any calculus text) is not greater than  $|d^4 x / dt^4|_{\max} [(t_1)^4 / 4!]$  ,  $0 \leq t \leq t_1$  .

### Picard's Method

If the vector differential equation  $\mathbf{x}' = f(t, \mathbf{x})$  ,  $\mathbf{x}(0)$  given, is to be approximated by Picard iteration, we begin with an initial guess  $\mathbf{x}_0 = \mathbf{x}(0)$  and calculate iteratively  $\mathbf{x}'_i = f(t, \mathbf{x}_{i-1})$  .

**Example 203.4.** Consider the equation  $x' = x + y^2$  ,  $y' = y - x^3$  ,  $x(0) = 1$  ,  $y(0) = 2$  . With  $x_0 = 1$  ,  $y_0 = 2$  ,  $x'_1 = 5$  ,  $y'_1 = 1$  , so  $x_1 = 5t + 1$  ,  $y_1 = t + 2$  , since  $x_i(0) = 1$  ,  $y_i(0) = 2$  for  $i \geq 0$  . To continue, use  $x'_{i+1} = x_i + y_i^2$  ,  $y'_{i+1} = y_i - x_i^3$  . A modification is the utilization of the first calculated term immediately in the second equation. Thus, the calculated value of  $x_1 = 5t + 1$  , when used in the second equation, gives  $y'_1 = y_0 - (5t + 1)^3 = 2 - (125t^3 + 75t^2 + 15t + 1)$  , so  $y_1 = 2t - (125t^4/4) - 25t^3 - (15t^2/2) - t + 2$  . Continue with the iteration  $x'_{i+1} = x_i + y_i^2$  ,  $y'_{i+1} = y_i - (x_{i+1})^3$  .

Another variation would be  $x'_{i+1} = x_{i+1} + (y_i)^2$  ,  $y'_{i+1} = y_{i+1} - (x_{i+1})^3$  .

All of the integral transforms are special cases of the equation  $g(s) = \int_a^b K(s, t)f(t) dt$ , in which  $g(s)$  is said to be the *transform* of  $f(t)$ , and  $K(s, t)$  is called the *kernel* of the transform. [Table 204.1](#) shows the more important kernels and the corresponding intervals  $(a, b)$ .

**Table 204.1** Kernels and Intervals of Various Integral Transforms

Name of Transform	$(a, b)$	$K(s, t)$
Laplace	$(0, \infty)$	$e^{-st}$
Fourier	$(-\infty, \infty)$	$\frac{1}{\sqrt{2\pi}}e^{-ist}$
Fourier cosine	$(0, \infty)$	$\sqrt{\frac{2}{\pi}} \cos st$
Fourier sine	$(0, \infty)$	$\sqrt{\frac{2}{\pi}} \sin st$
Mellin	$(0, \infty)$	$t^{s-1}$
Hankel	$(0, \infty)$	$tJ_v(st), \quad v \geq -\frac{1}{2}$

Details for the first three transforms listed in [Table 204.1](#) are given in this chapter. The details for the others are found in the literature.

**204.1 Laplace Transform**

The Laplace transform of  $f(t)$  is  $g(s) = \int_0^\infty e^{-st} f(t) dt$ . It may be thought of as transforming one class of functions into another. The advantage in the operation is that under certain circumstances it replaces complicated functions by simpler ones. The notation  $L[f(t)] = g(s)$  is called the *direct*

transform and  $L^{-1}[g(s)] = f(t)$  is called the *inverse transform*. Both the direct and inverse transforms are tabulated for many often-occurring functions. In general  $L^{-1}[g(s)] = (1/2\pi i) \int_{\alpha-i\infty}^{\alpha+i\infty} e^{st} g(s) ds$ , and to evaluate this integral requires a knowledge of complex variables, the theory of residues, and contour integration.

## Properties of the Laplace Transform

Let  $L[f(t)] = g(s)$ ,  $L^{-1}[g(s)] = f(t)$ .

1. The Laplace transform may be applied to a function  $f(t)$  if  $f(t)$  is continuous or piecewise continuous; if  $t^n |f(t)|$  is finite for all  $t$ ,  $t \rightarrow 0$ ,  $n < 1$ ; and if  $e^{-at} |f(t)|$  is finite as  $t \rightarrow \infty$  for some value of  $a$ ,  $a > 0$ .
2.  $L$  and  $L^{-1}$  are unique.
3.  $L[af(t) + bh(t)] = aL[f(t)] + bL[h(t)]$  (linearity).
4.  $L[e^{at} f(t)] = g(s - a)$  (shift theorem).
5.  $L[(-t)^k f(t)] = d^k g/ds^k$ ;  $k$  a positive integer.

**Example 204.1.**  $L[\sin at] = \int_0^\infty e^{-st} \sin at dt = a/(s^2 + a^2)$ ,  $s > 0$ . By property 5,

$$\int_0^\infty e^{-st} t \sin at dt = L[t \sin at] = \frac{2as}{s^2 + a^2}$$

6.

$$\begin{aligned} L[f'(t)] &= sL[f(t)] - f(0) \\ L[f''(t)] &= s^2 L[f(t)] - sf(0) - f'(0) \\ &\vdots \\ L[f^{(n)}(t)] &= s^n L[f(t)] - s^{n-1} f(0) - \dots - sf^{(n-2)}(0) - f^{(n-1)}(0) \end{aligned}$$

In this property it is apparent that the initial data are automatically brought into the computation.

**Example 204.2.** Solve  $y'' + y = e^t$ ,  $y(0) = 0$ ,  $y'(0) = 1$ . Now

$L[y''] = s^2 L[y] - sy(0) - y'(0) = s^2 L[y] - s - 1$ . Thus, using the linear property of the transform (property 3),  $s^2 L[y] + L[y] - s - 1 = L[e^t] = 1/(s - 1)$ . Therefore,  $L[y] = s^2 / [(s - 1)(s^2 + 1)]$ .

With the notations  $\Gamma(n + 1) = \int_0^\infty x^n e^{-x} dx$  (gamma function) and  $J_n(t)$  the Bessel function of the first kind of order  $n$ , a short table of Laplace transforms is given in [Table 204.2](#).

$$7. L\left[\int_a^t f(t) dt\right] = \frac{1}{s} L[f(t)] + \frac{1}{s} \int_a^0 f(t) dt.$$

**Example 204.3.** Find  $f(t)$  if  $L[f(t)] = (1/s^2) [1/(s^2 - a^2)]$ .  $L[1/a \sinh at] = 1/(s^2 - a^2)$ .  
Therefore,  $f(t) = \int_0^t [\int_0^t \frac{1}{a} \sinh at dt] dt = 1/a^2 [(\sinh at)/a - t]$ .

8.

$$L \left[ \frac{f(t)}{t} \right] = \int_s^\infty g(s) ds; \quad L \left[ \frac{f(t)}{t^k} \right] = \underbrace{\int_s^\infty \cdots \int_s^\infty}_{k \text{ integrals}} g(s) (ds)^k$$

**Example 204.4.**  $L[(\sin at)/t] = \int_s^\infty L[\sin at] ds = \int_s^\infty [a ds/(s^2 + a^2)] = \cot^{-1}(s/a)$ .

9. The *unit step function*  $u(t - a) = 0$  for  $t < a$  and 1 for  $t > a$ .  $L[u(t - a)] = e^{-as}/s$ .

10. The *unit impulse function* is  $\delta(a) = u'(t - a) = 1$  at  $t = a$  and 0 elsewhere.

$$L[u'(t - a)] = e^{-as}.$$

11.  $L^{-1}[e^{-as} g(s)] = f(t - a)u(t - a)$  (second shift theorem).

12. If  $f(t)$  is *periodic* of period  $b$  that is,  $f(t + b) = f(t)$  — then  $L[f(t)] = [1/(1 - e^{-bs})] \times \int_0^b e^{-st} f(t) dt$ .

**Example 204.5.** The equation  $\partial^2 y / (\partial t \partial x) + \partial y / \partial t + \partial y / \partial x = 0$  with  $(\partial y / \partial x)(0, x) = y(0, x) = 0$  and  $y(t, 0) + (\partial y / \partial t)(t, 0) = \delta(0)$  (see property 10) is solved by using the Laplace transform of  $y$  with respect to  $t$ . With  $g(s, x) = \int_0^\infty e^{-st} y(t, x) dt$ , the transformed equation becomes

$$s \frac{\partial g}{\partial x} - \frac{\partial y}{\partial x}(0, x) + sg - y(0, x) + \frac{\partial g}{\partial x} = 0$$

or

$$(s + 1) \frac{\partial g}{\partial x} + sg = \frac{\partial y}{\partial x}(0, x) + y(0, x) = 0$$

The second (boundary) condition gives  $g(s, 0) + sg(s, 0) - y(0, 0) = 1$  or  $g(s, 0) = 1/(1 + s)$ . A solution of the preceding ordinary differential equation consistent with this condition is  $g(s, x) = [1/(s + 1)] e^{-sx/(s+1)}$ . Inversion of this transform gives  $y(t, x) = e^{-(t+x)} I_0(2\sqrt{tx})$ , where  $I_0$  is the zero-order Bessel function of an imaginary argument.

**Table 204.2** Some Laplace Transforms

$f(t)$	$g(s)$	$f(t)$	$g(s)$
1	$\frac{1}{s}$	$e^{-at}(1 - at)$	$\frac{s}{(s + a)^2}$
$t^n, n \text{ is a + integer}$	$\frac{n!}{s^{n+1}}$	$\frac{t \sin at}{2a}$	$\frac{s}{(s^2 + a^2)^2}$

$t^n, n \neq a + \text{integer}$	$\frac{\Gamma(n+1)}{s^{n+1}}$	$\frac{1}{2a^2} \sin at \sinh at$	$\frac{s}{s^4 + 4a^4}$
$\cos at$	$\frac{s}{s^2 + a^2}$	$\cos at \cosh at$	$\frac{s^3}{s^4 + 4a^4}$
$\sin at$	$\frac{a}{s^2 + a^2}$	$\frac{1}{2a}(\sinh at + \sin at)$	$\frac{s^2}{s^4 - a^4}$
$\cosh at$	$\frac{s}{s^2 - a^2}$	$\frac{1}{2}(\cosh at + \cos at)$	$\frac{s^3}{s^4 - a^4}$
$\sinh at$	$\frac{a}{s^2 - a^2}$	$\frac{\sin at}{t}$	$\tan^{-1} \frac{a}{s}$
$e^{-at}$	$\frac{1}{s + a}$	$J_0(at)$	$\frac{1}{\sqrt{s^2 + a^2}}$
$e^{-bt} \cos at$	$\frac{s + b}{(s + b)^2 + a^2}$	$\frac{n}{a^n} \frac{J_n(at)}{t}$	$\frac{1}{(\sqrt{s^2 + a^2} + s)^n}$
$e^{-bt} \sin at$	$\frac{a}{(s + b)^2 + a^2}$	$J_0(2\sqrt{at})$	$\frac{1}{s} e^{-a/s}$

## 204.2 Convolution Integral

The *convolution integral* (*faltung*) of two functions  $f(t)$ ,  $r(t)$  is  
 $x(t) = f(t) * r(t) = \int_0^t f(\tau) r(t - \tau) d\tau$  .

**Example 204.6.**  $t * \sin t = \int_0^t \tau \sin(t - \tau) d\tau = t - \sin t$  .

$$13. L[f(t)]L[h(t)] = L[f(t) * h(t)] \quad .$$

## 204.3 Fourier Transform

The *Fourier transform* is given by  $F[f(t)] = (1/\sqrt{2\pi}) \int_{-\infty}^{\infty} f(t)e^{-ist} dt = g(s)$  and its *inverse* by  $F^{-1}[g(s)] = (1/\sqrt{2\pi}) \int_{-\infty}^{\infty} g(s)e^{ist} dt = f(t)$  . In brief, the condition for the Fourier transform to exist is that  $\int_{-\infty}^{\infty} |f(t)| dt < \infty$  , although certain functions may have a Fourier transform even if this is violated.

**Example 204.7.** The function  $f(t) = 1$  for  $-a \leq t \leq a$  and  $= 0$  elsewhere has

$$F[f(t)] = \int_{-a}^a e^{-ist} dt = \int_0^a e^{ist} dt + \int_0^a e^{-ist} dt = 2 \int_0^a \cos st dt = \frac{2 \sin sa}{s}$$

## Properties of the Fourier Transform

Let  $F[f(t)] = g(s)$  ;  $F^{-1}[g(s)] = f(t)$  .

$$1. F[f^{(n)}(t)] = (is)^n F[f(t)]$$

2.  $F[af(t) + bh(t)] = aF[f(t)] + bF[h(t)]$
3.  $F[f(-t)] = g(-s)$
4.  $F[f(at)] = 1/a g(s/a)$  ,  $a > 0$
5.  $F[e^{-iwt} f(t)] = g(s + w)$
6.  $F[f(t + t_1)] = e^{ist_1} g(s)$
7.  $F[f(t)] = G(is) + G(-is)$  if  $f(t) = f(-t)$  ( $f(t)$  even)  $F[f(t)] = G(is) - G(-is)$  if  $f(t) = -f(-t)$  ( $f$  odd)

where  $G(s) = L[f(t)]$  . This result allows the use of the Laplace transform tables to obtain the Fourier transforms.

**Example 204.8.** Find  $F[e^{-a|t|}]$  by property 7. The term  $e^{-a|t|}$  is even. So  $L[e^{-at}] = 1/(s + a)$  . Therefore,  $F[e^{-a|t|}] = 1/(is + a) + 1/(-is + a) = 2a/(s^2 + a^2)$  .

## 204.4 Fourier Cosine Transform

The *Fourier cosine transform* is given by  $F_c[f(t)] = g(s) = \sqrt{(2/\pi)} \int_0^\infty f(t) \cos st dt$  and its inverse by  $F_c^{-1}[g(s)] = f(t) = \sqrt{(2/\pi)} \int_0^\infty g(s) \cos st ds$  . The *Fourier sine transform*  $F_s$  is obtainable by replacing the cosine by the sine in the above integrals.

**Example 204.9.**  $F_c[f(t)]$ ,  $f(t) = 1$  for  $0 < t < a$  and 0 for  $a < t < \infty$  .  
 $F_c[f(t)] = \sqrt{(2/\pi)} \int_0^a \cos st dt = \sqrt{(2/\pi)} (\sin as)/s$  .

## Properties of the Fourier Cosine Transform

$F_c[f(t)] = g(s)$  .

1.  $F_c[af(t) + bh(t)] = aF_c[f(t)] + bF_c[h(t)]$
2.  $F_c[f(at)] = (1/a) g(s/a)$
3.  $F_c[f(at) \cos bt] = 1/2a [g((s + b)/a) + g((s - b)/a)]$  ,  $a, b > 0$
4.  $F_c[t^{2n} f(t)] = (-1)^n (d^{2n} g)/(ds^{2n})$
5.  $F_c[t^{2n+1} f(t)] = (-1)^n (d^{2n+1} g)/(ds^{2n+1}) F_s[f(t)]$

Table 204.3 presents some Fourier cosine transforms.

**Table 204.3**

$f(t)$	$\frac{g(s)}{\sqrt{2/\pi}}$
$\left. \begin{array}{ll} t & 0 < t < 1 \\ 2 - t & 1 < t < 2 \\ 0 & 2 < t < \infty \end{array} \right\}$	$\frac{1}{s^2} [2 \cos s - 1 - \cos 2s]$
$t^{-1/2}$	$\pi^{1/2} (2s)^{-1/2}$
$\left. \begin{array}{ll} 0 & 0 < t < a \\ (t - a)^{-1/2} & a < t < \infty \end{array} \right\}$	$\pi^{1/2} (2s)^{-1/2} [\cos as - \sin as]$
$(t^2 + a^2)^{-1}$	$\frac{1}{2} \pi a^{-1} e^{-as}$
$e^{-at}, \quad a > 0$	$\frac{a}{s^2 + a^2}$
$e^{-at^2}, \quad a > 0$	$\frac{1}{2} \pi^{1/2} a^{-1/2} e^{-s^2/4a}$
$\frac{\sin at}{t}, \quad a > 0$	$\begin{cases} \pi/2 & s < a \\ \pi/4 & s = a \\ 0 & s > a \end{cases}$

**Example 204.10.** The temperature  $\theta$  in the semiinfinite rod  $0 \leq x < \infty$  is determined by the differential equation  $\partial\theta/\partial t = k(\partial^2\theta/\partial x^2)$  and the condition  $\theta = 0$  when  $t = 0, x \geq 0$ ;  $\partial\theta/\partial x = -\mu = \text{constant}$  when  $x = 0, t > 0$ . By using the Fourier cosine transform, a solution may be found as  $\theta(x, t) = (2\mu/\pi) \int_0^\infty (\cos px/p) (1 - e^{-kp^2t}) dp$ .

# Chaos, Fractals, and Julia Sets

---

- 205.1 Chaos
- 205.2 Fractals
- 205.3 Julia Sets

## Anca Deliu

*Georgia Institute of Technology*

The mathematical foundations of chaotic dynamics go back about 100 years to the work of the French mathematician Henri Poincaré, who studied the time evolution of three celestial bodies subject to mutual gravitational forces. He showed that very irregular orbits (called *chaotic* in today's terminology) could arise due to the nonlinearities present in the problem.

The explosive interest in chaos (or nonlinear science) in the last two decades is largely due to the availability of powerful computers with high-quality graphics. Researchers from fields other than mathematics have become aware that simple and familiar phenomena from physics and engineering, as well as economics, biology, and geology, can lead to unpredictable time evolutions, despite their deterministic nature.

As opposed to classical systems, which eventually settle into periodic motion or steady state, chaotic systems evolve apparently at random on a fractal attractor. The complexity of the system is related to the geometry of the attractor. The study of individual trajectories becomes irrelevant and is replaced by a statistical analysis.

Examples of attractors discovered in recent years are the Lorentz attractor, the Henon attractor, and the Smale horseshoe attractor [[Falconer, 1990](#)].

In addition to these are the classical Cantor and Julia sets which, one might say, are old examples for a new science [[Barnsley, 1988](#)].

## 205.1 Chaos

---

The goal of the study of dynamical systems is to determine the long-time evolution of the system. In practice one analyzes the evolution of an observable (a measurement)  $x$ , associated with the system, such as temperature, pressure, or population. According to whether time is discrete or continuous, we have discrete or continuous dynamical systems. Chaotic behavior can occur in continuous systems with phase spaces of dimension  $\geq 3$  and in discrete systems in dimension  $\geq 1$ .

Consider the difference equation

$$x_{n+1} = f(x_n) \quad (205.1)$$

where  $X \subset \mathbb{R}^n$  and  $f : X \rightarrow X$ , a mapping with some regularity. The pair  $(f, X)$  is a *discrete dynamical system* with *phase space*  $X$ . The orbit of  $x_0 \in X$  is the sequence of iterates  $x_k = f^k(x_0) : k \geq 0$ . The term  $x_k$  represents the value of the observable  $x$  at time  $k$ .

A point  $y$  is a *periodic point* of *period*  $p$  if  $f^p(y) = y$ . Then  $y$  has a *periodic orbit* consisting of finitely many points  $\{y, f(y), \dots, f^{p-1}(y)\}$ . A periodic point of period 0 is called a *fixed point*. Periodic points play an important role in understanding the dynamics of  $f$ .

**Example 205.1.** Let  $X = \mathbb{R}$  and  $f(x) = \cos x$ . Then the orbits of all  $x_0 \in \mathbb{R}$  converge to the unique fixed point of  $\cos x$ ,  $x \approx 0.739$ , as one can check by pressing repeatedly the  $\cos$  button on a calculator.

A closed and bounded subset  $A \subset X$  is an *attractor* if  $A$  is *invariant*—that is,  $f(A) = A$ —and  $A$  is *attracting*—that is, the distance between  $f^k(x_0)$  and  $A$  converges to zero as  $k \rightarrow \infty$ —for all points  $x_0 \in V$  in some neighborhood  $V$  of  $A$ . The set  $V$  is called the *basin of attraction* of  $A$ .

A *repeller* for  $f$  is a closed bounded set from which nearby initial conditions are running away under iteration. Speaking loosely, one can identify attractors and repellers by reversing the arrow of time.

A fractal attractor is called a *strange attractor* [Ruelle and Takens, 1971] to explain the onset of turbulence.

Dynamics on a strange attractor is usually chaotic. The word *chaos* was introduced by Li and Yorke. They proved that if a map has period 3 then it has all other periods; they summarized this result in the title of the paper, "Period Three Implies Chaos" [Li and Yorke, 1975]. The current technical meaning of *chaos* is, however, different.

We say that  $f$  is *chaotic* if the following three conditions hold.

1. There is a point  $x$  whose orbit is dense in  $A$ —that is, it comes arbitrarily close to any point in  $A$ .
2. The periodic points of  $f$  are dense in  $A$ .
3. The function  $f$  has sensitive dependence on initial conditions; that is, there is a number  $\delta > 0$ , such that for any  $x \in X$  there are points  $y$  arbitrarily close to  $x$ , such that  $|f^k(x) - f^k(y)| \geq \delta$  for some  $k$ .

It is convenient sometimes to study a whole family of dynamical systems,  $(X, f_\lambda)$ , indexed by an experimental control parameter  $\lambda$ . Varying  $\lambda$  changes the quality of the dynamics (the geometric nature of the attractor) through a sequence of transitions that may lead to chaos (turbulence). Several scenarios for the onset of chaos have been proposed [Ruelle, 1989]:

1. Ruelle-Takens scenario through quasiperiodicity
2. Feigenbaum scenario through periodic doubling
3. Pomeau-Manneville scenario through intermittency

The next example illustrates scenario 2.

**Example 205.2.** Let  $X = [0, 1]$  and let  $f_\lambda : X \rightarrow X$  be the logistic family  $f_\lambda(x) = \lambda x(1 - x)$  (205.2)

originally introduced to model the development of certain populations. If the population is  $x_k$  at the end of the  $k$ th year, it is assumed to be  $x_{k+1} = f_\lambda(x_k)$  at the end of the  $(k + 1)$  th year.

As  $\lambda$  increases from 0 to 4,  $f_\lambda$  presents a wide spectrum of behavior, ranging from the simplest to the most complex. [Falconer, 1990, p. 176] .

For  $0 < \lambda < 3$  ,  $f$  has a stable fixed point,  $x_\lambda = 1 - 1/\lambda$  , which attracts all orbits starting at  $x_0 \in (0, 1)$  .

When  $\lambda$  increases through the value  $\lambda = \lambda_1 = 3$  , the stable fixed point  $x_\lambda$  splits into a stable period 2 orbit,  $\{y_\lambda^1, y_\lambda^2\}$  . For example, if  $\lambda = 3.38$  , almost all trajectories settle asymptotically into this periodic cycle.

At  $\lambda = \lambda_2 = 1 + \sqrt{6} \approx 3.45$  , the period 2 orbit becomes unstable and splits into a stable period 4 orbit. Let  $\lambda_k$  denote the value of  $\lambda$  at which the  $k$ th period doubling occurs. Then  $\lambda_k$  increases to the critical value  $\lambda_\infty \approx 3.57$  , where chaos sets in.

For  $\lambda \in (\lambda_\infty, 4)$  chaos and periodicity alternate, depending on specific window values of  $\lambda$ .

Feigenbaum discovered that  $\lambda_\infty$  is a universal constant, in the sense that

$$\lambda_\infty - \lambda_k \approx C\delta^k \quad (205.3)$$

for very general families of functions.

If the time step is allowed to converge to zero, Eq. (205.1) becomes an autonomous (time-independent) differential equation,

$$\frac{dx}{dt} = f(x)$$

which determines a *continuous dynamical system* . The family of solution curves corresponding to various initial conditions  $x_0 \in X$  represents the trajectories on which the system evolves as time  $t \rightarrow \pm\infty$  .

**Example 205.3.** The most famous continuous system with chaotic behavior is described by Lorentz [1963], who studied Rayleigh-Benard convection. A fluid contained between two rigid plates is subjected to gravity. The top plate is maintained at the temperature  $T_0$  and the bottom plate is maintained at a higher temperature,  $T_0 + \Delta T$  . Experiment shows that, for a certain range of small values of  $\Delta T$  , the fluid will execute a convective cellular flow. For bigger values of  $\Delta T$  the flow becomes chaotic. This is similar to what happens in the earth's atmosphere. The specific equations of Lorentz are

$$\frac{dx}{dt} = -\sigma x + \sigma y$$

$$\frac{dy}{dt} = -xy + rx - y$$

$$\frac{dz}{dt} = xy - bz$$

where  $\sigma = 10$ ,  $r = 28$ , and  $b = 8/3$ .

The system has sensitive dependence on initial conditions: Orbits that start close soon become uncorrelated, which explains the well-observed fact that the weather is essentially unpredictable for periods longer than five days.

The Lorentz strange attractor lives in  $R^3$  and its two-dimensional projections have a characteristic butterfly shape [Falconer, 1990].

## 205.2 Fractals

---

The term *fractal* was coined by Mandelbrot [1982] to denote sets with fractured structure. He proposed the idea that fractals are the rule rather than the exception in nature: trees, coastlines, flames, riverbeds, and so forth all exhibit fractal behavior.

A fractal is a set whose topological dimension is *strictly* smaller than its Hausdorff dimension.

The topological dimension,  $\text{TDim}$ , of a set takes only integer values and is, roughly speaking, what we intuitively mean by dimension:  $\text{TDim}(\text{point}) = 0$ ;  $\text{TDim}(\text{continuous curve}) = 1$ ;  $\text{TDim}(\text{surface}) = 2$ , and so forth.

The Hausdorff dimension provides a way to distinguish between topologically equivalent attractors with various levels of geometric complexity.

The diameter of  $U \subset R^n$  is  $|U| = \sup\{|x - y| : x, y \in U\}$ . Let  $F \subset R^n$ . For  $\varepsilon > 0$ , an  $\varepsilon$ -cover of  $F$  is any countable collection of sets  $U_i$  with  $|U_i| < \varepsilon$ , and such that  $F \subset \cup_i U_i$ . Let  $s \geq 0$ . For any  $\varepsilon > 0$ , we define

$$\mathcal{H}_\varepsilon^s(F) = \inf \left\{ \sum_{i=1}^{\infty} |U_i|^s : \{U_i\} \text{ is an } \varepsilon\text{-cover of } F \right\}$$

As  $\varepsilon$  decreases to 0,  $\mathcal{H}_\varepsilon^s(F)$  increases and thus approaches a limit,

$$\mathcal{H}^s(F) = \lim_{\varepsilon \rightarrow 0} \mathcal{H}_\varepsilon^s(F)$$

which we define to be the *s-dimensional Hausdorff measure* of  $F$ .

For any subset  $F \subset R^n$ , there is a unique number  $D = \text{HDim}(F) \geq 0$  such that for  $0 \leq s < D$ ,  $\mathcal{H}^s(F) = \infty$  and for  $D < s < \infty$ ,  $\mathcal{H}^s(F) = 0$ . This number  $D$  is called the *Hausdorff dimension* of  $F$ . If  $F$  has Hausdorff dimension  $D$ , the  $D$ -dimensional Hausdorff measure of  $F$  may take any value in  $[0, \infty]$ . It always holds that  $\text{TDim} \leq \text{HDim}$ .

The Hausdorff dimension is difficult to estimate, both theoretically and numerically. As a substitute, one often uses a simpler concept, the *fractal dimension*, which conveys similar information about the geometry of a set yet is easier to compute.

Let  $F \subset R^n$  be a nonempty bounded subset of some euclidian space, and let  $\mathcal{N}(F, \varepsilon)$  be the smallest number of cubes of side length equal to  $\varepsilon$  required to cover  $F$ . The fractal dimension (also called *box dimension*, *Kolmogorov entropy*, or *capacity*) is defined as the limit

$$\text{FDim}(F) = \lim_{\varepsilon \rightarrow 0} \frac{\log \mathcal{N}(F, \varepsilon)}{-\log \varepsilon}$$

For any set,  $\text{TDim} \leq \text{HDim} \leq \text{FDim}$  .

The dimension of the Lorentz attractor was estimated numerically to be around 2.04 and the dimension of the attractor corresponding to  $\lambda_\infty$  , from Example 205.2, was estimated numerically to be  $\approx 0.538$  [ [Falconer, 1990, p. 175](#)].

The only class of fractals whose dimension is given by a simple formula is that of *self-similar sets*.

A map  $W : R^n \rightarrow R^n$  is called a *contractive similitude* if  $|W(x) - W(y)| = s|x - y|$  , for any  $x, y \in R^n$  , for some  $0 < s < 1$  . The number  $s$  is the *contraction ratio* of  $W$ .

A set  $A \subset R^n$  is *self-similar* if it can be tiled with smaller copies of itself,

$$A = \cup_{i=1}^N W_i(A) \quad (205.4)$$

where  $\{W_i\}$  are contractive similitudes.

If the nonoverlapping condition  $W_i(A) \cap W_j(A) = \emptyset$  holds, then

$$\text{HDim}(A) = \text{FDim}(A) = D \quad (205.5)$$

where  $D$  is the unique real solution to the equation  $\sum_{i=1}^N s_i^D = 1$  and  $s_i$  is the contraction ratio of  $W_i$ .

The simplest example of a self-similar set is the ternary Cantor set  $C$  ([Fig. 205.1](#)). From the closed interval  $[0, 1]$  , remove the middle third interval  $(\frac{1}{3}, \frac{2}{3})$  . Two closed intervals remain— $[0, \frac{1}{3}]$  and  $[\frac{2}{3}, 1]$  . Repeat the procedure for all remaining intervals iteratively. The Cantor set  $C$  is the fractal "dust" that remains. All points of the form  $\{k3^{-n} : n \geq 0, 0 \leq k \leq 3^n - 1\}$  belong to  $C$ , but there are many more.

**Figure 205.1** Ternary Cantor set  $C$ .

[Figure 205.2](#) illustrates the analogous two-dimensional construction, which is easier to picture.

**Figure 205.2** Two-dimensional construction of Cantor set  $C$ .

For the Cantor set in Fig. 205.1,  $W_1 = x/3$  and  $W_2 = x/3 + 2/3$ ,  $s_1 = s_2 = 1/3$ , hence Eq. (205.5) yields  $\text{HDim}(C) = \text{FDim}(C) = \log 2 / \log 3$ . For the Cantor set in Fig. 205.2,  $N = 4$ ,  $\{s_i = 1/3 : i = 1, \dots, 4\}$  and Eq. (205.5) yields  $\text{HDim} = \text{FDim} = \log 4 / \log 3$ . The topological dimension of both Cantor sets is 0, a feature common to all "dust" (*totally disconnected*) sets.

## 205.3 Julia Sets

Julia sets are fractals with most singular shapes that are generated by the iteration of simple complex mappings. For instance, consider the quadratic polynomials  $f(z) = z^2 + c$ ,  $z \in C$ ,  $c \in C$  a complex parameter.

The *Julia set*  $J(f)$  of  $f$  is the closure of the set of repelling periodic points of  $f$ . The complement of the Julia set is called the *Fatou* (or *stable*) set. One can show that  $J(f)$  is nonempty, is closed and bounded, has empty interior, and is generally a fractal. The Julia set  $J = J(f)$  is both forward- and backward-invariant,  $J = f(J) = f^{-1}(J)$ , and  $f$  is chaotic on  $J$ .

**Example 205.4.** For  $c = 0$ ,  $f(z) = z^2$  and the corresponding Julia set  $J(f)$  is the unit circle  $\{|z| = 1\}$ .

**Example 205.5.** Let  $c \neq 0$  be a complex number so that  $|c|$  is small. Then the Julia set  $J(f)$  is a closed fractal curve, close to the unit circle.

In these two examples  $J(f)$  is the boundary between two regions of  $\mathbb{C}$  with distinct behaviors: if  $z_0$  is inside the Julia set curve, the iterates  $f^k(z_0)$  converge to the finite fixed point of  $f$ , and if  $z_0$  is outside the curve its iterates diverge to  $\infty$ .

One can show that if  $|c| < \frac{1}{4}$  then  $J(f)$  is a closed curve, whereas if  $|c| > \frac{1}{4}(5 + 2\sqrt{6})$ ,  $J(f)$  is totally disconnected. For several pictures of Julia sets, see [Falconer 1990, p. 214].

[206.1 The Euler Equation](#)[206.2 The Variation](#)[206.3 Constraints](#)**William F. Ames***Georgia Institute of Technology*

The basic problem in the *calculus of variations* is to determine a function such that a certain *functional*, often an integral involving that function and certain of its derivatives, takes on *maximum or minimum values*. As an example, find the function  $y(x)$  such that  $y(x_1) = y_1$ ,  $y(x_2) = y_2$  and the integral (functional)  $I = 2\pi \int_{x_1}^{x_2} y[1 + (y')^2]^{1/2} dx$  is a minimum. A second example concerns the transverse deformation  $u(x, t)$  of a beam. The energy functional  $I = \int_{t_1}^{t_2} \int_0^L [\frac{1}{2} \rho (\partial u / \partial t)^2 - \frac{1}{2} EI (\partial^2 u / \partial x^2)^2 + fu] dx dt$  is to be minimized.

---

**206.1 The Euler Equation**

---

The elementary part of the theory is concerned with a *necessary* condition (generally in the form of a differential equation with boundary conditions) that the required function must satisfy. To show mathematically that the function obtained actually maximizes (or minimizes) the integral is much more difficult than the corresponding problems of the differential calculus.

The *simplest case* is to determine a function  $y(x)$  that makes the integral  $I = \int_{x_1}^{x_2} F(x, y, y') dx$  stationary and that satisfies the prescribed end conditions  $y(x_1) = y_1$  and  $y(x_2) = y_2$ . Here we suppose  $F$  has continuous second partial derivatives with respect to  $x$ ,  $y$ , and  $y' = dy/dx$ . If  $y(x)$  is such a function, then it must satisfy the *Euler equation*  $(d/dx)(\partial F / \partial y') - (\partial F / \partial y) = 0$ , which is the required necessary condition. The indicated partial derivatives have been formed by treating  $x$ ,  $y$ , and  $y'$  as independent variables. Expanding the equation, the equivalent form

$F_{y'y'} y'' + F_{y'y} y' + (F_{y'x} - F_y) = 0$  is found. This is second order in  $y$  unless

$F_{y'y'} = (\partial^2 F) / [(\partial y')^2] = 0$ . An alternative form

$1/y' [d/dx(F - (\partial F / \partial y')(dy/dx)) - (\partial F / \partial x)] = 0$  is useful. Clearly, if  $F$  does not involve  $x$  explicitly  $[(\partial F / \partial x) = 0]$  a first integral of Euler's equation is  $F - y' (\partial F / \partial y') = c$ . If  $F$  does not involve  $y$  explicitly  $[(\partial F / \partial y) = 0]$  a first integral is  $(\partial F / \partial y') = c$ .

The Euler equation for  $I = 2\pi \int_{x_1}^{x_2} y[1 + (y')^2]^{1/2} dx$ ,  $y(x_1) = y_1$ ,  $y(x_2) = y_2$  is  $(d/dx) [yy' / [1 + (y')^2]^{1/2}] - [1 + (y')^2]^{1/2} = 0$  or after reduction  $yy'' - (y')^2 - 1 = 0$ . The

solution is  $y = c_1 \cosh(x/c_1 + c_2)$ , where  $c_1$  and  $c_2$  are integration constants. Thus the required minimal surface, if it exists, must be obtained by revolving a catenary. Can  $c_1$  and  $c_2$  be chosen so that the solution passes through the assigned points? The answer is found in the solution of a transcendental equation that has two, one, or no solutions, depending on the prescribed values of  $y_1$  and  $y_2$ .

## 206.2 The Variation

If  $F = F(x, y, y')$ , with  $x$  independent and  $y = y(x)$ , then the *first variation*  $\delta F$  of  $F$  is defined to be  $\delta F = (\partial F / \partial x) \delta y + (\partial F / \partial y) \delta y'$  and  $\delta y' = \delta(dy/dx) = (d/dx)(\delta y)$ ; —that is, they commute. Note that the first variation,  $\delta F$ , of a functional is a first-order change from curve to curve, whereas the differential of a function is a first-order approximation to the change in that function along a *particular curve*. The laws of  $\delta$  are as follows:  $\delta(c_1 F + c_2 G) = c_1 \delta F + c_2 \delta G$ ;  $\delta(FG) = F \delta G + G \delta F$ ;  $\delta(F/G) = (G \delta F - F \delta G)/G^2$ ; if  $x$  is an independent variable,  $\delta x = 0$ ; if  $u = u(x, y)$ ;  $(\partial/\partial x)(\delta u) = \delta(\partial u/\partial x)$ ,  $(\partial/\partial y)(\delta u) = \delta(\partial u/\partial y)$ .

A necessary condition that the integral  $I = \int_{x_1}^{x_2} F(x, y, y') dx$  be stationary is that its (first) variation vanish—that is,  $\delta I = \delta \int_{x_1}^{x_2} F(x, y, y') dx = 0$ . Carrying out the variation and integrating by parts yields  $\delta I = \int_{x_1}^{x_2} [(\partial F/\partial y) - (d/dx)(\partial F/\partial y')] \delta y dx + [(\partial F/\partial y') \delta y]_{x_1}^{x_2} = 0$ . The arbitrary nature of  $\delta y$  means the square bracket must vanish and the last term constitutes the *natural boundary conditions*.

**Example.** The Euler equation of  $\int_{x_1}^{x_2} F(x, y, y', y'') dx$  is  $(d^2/dx^2)(\partial F/\partial y'') - (d/dx)(\partial F/\partial y') + (\partial F/\partial y) = 0$ , with natural boundary conditions  $\{[(d/dx)(\partial F/\partial y'') - (\partial F/\partial y')] \delta y\}_{x_1}^{x_2} = 0$  and  $(\partial F/\partial y'') \delta y' g|_{x_1}^{x_2} = 0$ . The Euler equation of  $\int_{x_1}^{x_2} \int_{y_1}^{y_2} F(x, y, u, u_x, u_y, u_{xx}, u_{xy}, u_{yy}) dx dy$  is  $(\partial^2/\partial x^2)(\partial F/\partial u_{xx}) + (\partial^2/\partial x \partial y)(\partial F/\partial u_{xy}) + (\partial^2/\partial y^2)(\partial F/\partial u_{yy}) - (\partial/\partial x)(\partial F/\partial u_x) - (\partial/\partial y)(\partial F/\partial u_y) + (\partial F/\partial u) = 0$ , and the natural boundary conditions are

$$\left[ \left( \frac{\partial}{\partial x} \left( \frac{\partial F}{\partial u_{xx}} \right) + \frac{\partial}{\partial y} \left( \frac{\partial F}{\partial u_{xy}} \right) - \frac{\partial F}{\partial u_x} \right) \delta u \right]_{x_1}^{x_2} = 0, \quad \left[ \left( \frac{\partial F}{\partial u_{xx}} \right) \delta u_x \right]_{x_1}^{x_2} = 0$$

$$\left[ \left( \frac{\partial}{\partial y} \left( \frac{\partial F}{\partial u_{yy}} \right) + \frac{\partial}{\partial x} \left( \frac{\partial F}{\partial u_{xy}} \right) - \frac{\partial F}{\partial u_y} \right) \delta u \right]_{y_1}^{y_2} = 0, \quad \left[ \left( \frac{\partial F}{\partial u_{yy}} \right) \delta u_y \right]_{y_1}^{y_2} = 0$$

In the more general case of  $I = \iiint_R F(x, y, u, v, u_x, u_y, v_x, v_y) dx dy dz$ , the condition  $\delta I = 0$  gives rise to the two Euler equations  $(\partial/\partial x)(\partial F/\partial u_x) + (\partial/\partial y)(\partial F/\partial u_y) - (\partial F/\partial u) = 0$  and  $(\partial/\partial x)(\partial F/\partial v_x) + (\partial/\partial y)(\partial F/\partial v_y) - (\partial F/\partial v) = 0$ . These are two PDEs in  $u$  and  $v$  that are linear or quasi-linear in  $u$  and  $v$ . The Euler equation for  $I = \iiint_R (u_x^2 + u_y^2 + u_z^2) dx dy dz$ , from  $\delta I = 0$ , is Laplace's equation  $u_{xx} + u_{yy} + u_{zz} = 0$ .

Variational problems are easily derived from the differential equation and associated boundary conditions by multiplying by the variation and integrating the appropriate number of times. To illustrate, let  $F(x)$ ,  $\rho(x)$ ,  $p(x)$ , and  $w$  be the tension, the linear mass density, the natural load, and (constant) angular velocity of a rotating string of length  $L$ . The equation of motion is  $(d/dx)[F(dy/dx)] + \rho w^2 y + p = 0$ . To formulate a corresponding variational problem, multiply all terms by a variation  $\delta y$  and integrate over  $(0, L)$  to obtain

$$\int_0^L \frac{d}{dx} \left( F \frac{dy}{dx} \right) \delta y dx + \int_0^L \rho w^2 y \delta y dx + \int_0^L p \delta y dx = 0$$

The second and third integrals are the variations of  $\frac{1}{2} \rho w^2 y^2$  and  $py$ , respectively. To treat the first integral, integrate by parts to obtain

$$\left[ F \frac{dy}{dx} \delta y \right]_0^L - \int_0^L F \frac{dy}{dx} \delta \frac{dy}{dx} dx = \left[ F \frac{dy}{dx} \delta y \right]_0^L - \int_0^L \frac{1}{2} F \delta \left( \frac{dy}{dx} \right)^2 dx = 0$$

So the variation formulation is

$$\delta \int_0^L \left[ \frac{1}{2} \rho w^2 y^2 + py - \frac{1}{2} F \left( \frac{dy}{dx} \right)^2 \right] dx + \left[ F \frac{dy}{dx} \delta y \right]_0^L = 0$$

The last term represents the *natural boundary conditions*. The term  $\frac{1}{2} \rho w^2 y^2$  is the kinetic energy per unit length, the term  $-py$  is the potential energy per unit length due to the radial force  $p(x)$ , and the term  $\frac{1}{2} F(dy/dx)^2$  is a first approximation to the potential energy per unit length due to the tension  $F(x)$  in the string. Thus the integral is often called the *energy integral*.

## 206.3 Constraints

The variations in some cases cannot be arbitrarily assigned because of one or more auxiliary conditions that are usually called *constraints*. A typical case is the functional  $\int_{x_1}^{x_2} F(x, u, v, u_x, v_x) dx$  with a constraint  $\phi(u, v) = 0$  relating  $u$  and  $v$ . If the variations of  $u$  and  $v$  ( $\delta u$  and  $\delta v$ ) vanish at the end points, then the variation of the integral becomes

$$\int_{x_1}^{x_2} \left\{ \left[ \frac{\partial F}{\partial u} - \frac{d}{dx} \left( \frac{\partial F}{\partial u_x} \right) \right] \delta u + \left[ \frac{\partial F}{\partial v} - \frac{d}{dx} \left( \frac{\partial F}{\partial v_x} \right) \right] \delta v \right\} dx = 0$$

The variation of the constraint  $\phi(u, v) = 0$ ,  $\phi_u \delta u + \phi_v \delta v = 0$  means that the variations cannot both be assigned arbitrarily inside  $(x_1, x_2)$ , so their coefficients need not vanish separately.

Multiply  $\phi_u \delta u + \phi_v \delta v = 0$  by a Lagrange multiplier  $\lambda$  (may be a function of  $x$ ) and integrate to find  $\int_{x_1}^{x_2} (\lambda \phi_u \delta u + \lambda \phi_v \delta v) dx = 0$ . Adding this to the previous result yields

$$\int_{x_1}^{x_2} \left\{ \left[ \frac{\partial F}{\partial u} - \frac{d}{dx} \left( \frac{\partial F}{\partial u_x} \right) + \lambda \phi_u \right] \delta u + \left[ \frac{\partial F}{\partial v} - \frac{d}{dx} \left( \frac{\partial F}{\partial v_x} \right) + \lambda \phi_v \right] \delta v \right\} dx = 0$$

which must hold for any  $\lambda$ . Assign  $\lambda$  so the first square bracket vanishes. Then  $\delta v$  can be assigned to vanish inside  $(x_1, x_2)$ , so the two systems

$$\frac{d}{dx} \left[ \frac{\partial F}{\partial u_x} \right] - \frac{\partial F}{\partial u} - \lambda \phi_u = 0, \quad \frac{d}{dx} \left[ \frac{\partial F}{\partial v_x} \right] - \frac{\partial F}{\partial v} - \lambda \phi_v = 0$$

plus the constraint  $\phi(u, v) = 0$  are three equations for  $u$ ,  $v$  and  $\lambda$ .

In most engineering experiments, the outcomes (and hence the observed data) appear in a random and nondeterministic fashion. For example, the operating time of a system before failure, the tensile strength of a certain type of material, and the number of defective items in a batch of produced items are all subject to random variations from one experiment to another. In engineering statistics, we apply the theory and methods of statistics to develop procedures for summarizing the data and making statistical inference and to obtain useful information with the presence of randomness and uncertainty.

---

**207.1 Elementary Probability**

---

**Random Variables and Probability Distributions**

Intuitively speaking, a random variable (denoted by  $X$ ,  $Y$ ,  $Z$ , etc.) takes a numerical value that depends on the outcome of the experiment. Because the outcome of an experiment is subject to random variation, the resulting numerical value is also random. In order to provide a stochastic model for describing the probability distribution of a random variable  $X$ , we generally classify random variables into two groups—the discrete type and the continuous type. The discrete random variables are those which, technically speaking, take a finite number or a countably infinite number

of possible numerical values (in most engineering applications, they take nonnegative integer values). Continuous random variables involve outcome variables such as time, length, distance, area, and volume. We specify a function  $f(x)$ , called the probability density function (p.d.f.) of a random variable  $X$ , such that the probability that the random variable  $X$  takes a value in a set  $A$  (of real numbers) is given by

$$P[X \in A] = \begin{cases} \sum_{x \in A} f(x) & \text{for all sets } A \text{ if } X \text{ is discrete} \\ \int_A f(x) dx & \text{for all intervals } A \text{ if } X \text{ is continuous} \end{cases} \quad (207.1)$$

By letting  $A$  be the set of all values that are less than or equal to a fixed number  $t$  (i.e.,  $A = (-\infty, t]$ ), the probability function  $P[X \leq t]$ , denoted by  $F(t)$ , is called the distribution function of  $X$ . We note that, by calculus, if  $X$  is a continuous random variable and if  $F(x)$  is differentiable, then  $f(x) = (d/dx)F(x)$ .

## Expectations

In many applications, the result of an experiment with a numerical outcome  $X$  is a specific function of  $X[u(X)$ , say]. Because  $X$  is a random variable,  $u(X)$  itself is also a random variable. We define the expected value of  $u(X)$  by

$$E[u(X)] = \begin{cases} \sum_x u(x)f(x) & \text{if } X \text{ is discrete} \\ \int_{-\infty}^{\infty} u(x)f(x) dx & \text{if } X \text{ is continuous} \end{cases} \quad (207.2)$$

provided that, of course, the sum or the integral exists. In particular, if  $u(x) = x$ , then  $E(X) \equiv \mu$  is called the mean of  $X$  (of the distribution) and  $E(X - \mu)^2 \equiv \sigma^2$  is called the variance of  $X$  (of the distribution). The mean is a measurement of the central tendency, and the variance is a measurement of the dispersion of the distribution.

## Some Commonly Used Distributions

There are many well-known distributions which are useful in engineering statistics. Among the discrete distributions, the hypergeometric and binomial distributions have applications in acceptance sampling problems and quality control, and the Poisson distribution is useful for studying queueing theory and other related problems. Among the continuous distributions, the uniform distribution concerns random numbers and can be applied in simulation studies, the exponential and gamma distributions are closely related to the Poisson distribution and, together with the Weibull distribution, have important applications in life testing and reliability studies. All of these distributions involve at least one unknown parameter; hence their means and variances also depend on the parameters. The reader is referred to textbooks in this area for details. For example, Hahn and Shapiro [1967, pp. 163–169 and pp. 120–134] comprehensively list these and other distributions on their p.d.f.s and the graphs, parameters, means, variances, with discussions and examples of their applications.

## The Normal Distribution

Perhaps *the* most important distribution in statistics and probability is the normal distribution (also known as the Gaussian distribution). This distribution involves two parameters,  $\mu$  and  $\sigma^2$ , and its p.d.f. is given by

$$f(x) = f(x; \mu, \sigma^2) = \frac{1}{\sqrt{2\pi}\sigma} e^{-\frac{1}{2\sigma^2}(x-\mu)^2} \quad (207.3)$$

for  $-\infty < \mu < \infty$ ,  $\sigma^2 > 0$ , and  $-\infty < x < \infty$ . It can be shown that, for a p.d.f. of this form, the values of  $\mu$  and  $\sigma^2$  are, respectively, that of the mean and the variance of the distribution. Further, the quantity  $\sigma = \sqrt{\sigma^2}$  is called the standard deviation of the distribution. We shall use the symbol  $X \sim \mathcal{N}(\mu, \sigma^2)$  to denote that  $X$  has a normal distribution with mean  $\mu$  and variance  $\sigma^2$ .

When plotting the p.d.f.  $f(x; \mu, \sigma^2)$  given in Eq. (207.3), we see that the resulting graph represents a bell-shaped curve and is symmetric about  $\mu$ . If a random variable  $Z$  has an  $\mathcal{N}(0, 1)$  distribution, then the p.d.f. of  $Z$  is given by [from Eq. (207.3)]

$$\phi(z) = \frac{1}{\sqrt{2\pi}} e^{-\frac{1}{2}z^2}, \quad -\infty < z < \infty \quad (207.4)$$

The distribution function of  $Z$ ,

$$\Phi(z) = \int_{-\infty}^z \phi(u) du, \quad -\infty < z < \infty \quad (207.5)$$

cannot be given in a closed form; hence it has been tabulated. The table of  $\Phi(z)$  can be found in most textbooks in statistics and probability, including those listed in the references at the end of this chapter (we note in passing that, by the symmetry property,  $\Phi(z) + \Phi(-z) = 1$  holds for all  $z$ ).

## 207.2 Random Sample and Sampling Distributions

---

### Random Sample and Related Statistics

As noted in Box, Hunter, and Hunter [1978], in the design and analysis of engineering experiments, a study usually involves the following steps:

- (i) The choice of a suitable stochastic model by assuming that the observations follow a certain distribution. The functional form of the distribution (or the p.d.f.) is assumed to be known except the value(s) of the parameter(s).
- (ii) Design of experiments and collection of data.
- (iii) Summarization of data and computation of certain statistics.

(iv) Statistical inference (including the estimation of the parameters of the underlying distribution and the hypothesis-testing problems).

In order to make statistical inference concerning the parameter(s) of a distribution, it is essential to first study the sampling distributions. We say that  $X_1, X_2, \dots, X_n$  represent a random sample of size  $n$  if they are independent random variables and each of them has the same p.d.f.  $f(x)$ . (Due to space limitations, the notion of independence will not be carefully discussed here. But, nevertheless, we say that  $X_1, X_2, \dots, X_n$  are independent if

$$P[X_1 \in A_1, X_2 \in A_2, \dots, X_n \in A_n] = \prod_{i=1}^n P[X_i \in A_i] \quad (207.6)$$

holds for all sets  $A_1, A_2, \dots, A_n$ .) Because the parameters of the population are unknown, the population mean  $\mu$  and the population variance  $\sigma^2$  are unknown. In most commonly used distributions,  $\mu$  and  $\sigma^2$  can be estimated by the sample mean  $\bar{X}$  and the sample variance  $S^2$ , respectively, which are given by

$$\bar{X} = \frac{1}{n} \sum_{i=1}^n X_i, \quad S^2 = \frac{1}{n-1} \sum_{i=1}^n (X_i - \bar{X})^2 = \frac{1}{n-1} \left[ \sum_{i=1}^n X_i^2 - n\bar{X}^2 \right] \quad (207.7)$$

(The second equality in the formula for  $S^2$  can be verified algebraically.) Now, because  $X_1, X_2, \dots, X_n$  are random variables,  $\bar{X}$  and  $S^2$  are also random variables. Each of them is called a statistic and has a probability distribution which also involves the unknown parameter(s). In probability theory, there are two fundamental results concerning their distributional properties.

**Theorem 1.**

(Weak Law of Large Numbers). As the sample size  $n$  becomes large,  $\bar{X}$  converges to  $\mu$  in probability and  $S^2$  converges to  $\sigma^2$  in probability. More precisely, for every fixed positive number  $\varepsilon > 0$ , we have

$$P[|\bar{X} - \mu| \leq \varepsilon] \rightarrow 1, \quad P[|S^2 - \sigma^2| \leq \varepsilon] \rightarrow 1 \quad (207.8)$$

as  $n \rightarrow \infty$ .

**Theorem 2.**

(Central Limit Theorem). As  $n$  becomes large, the distribution of the random variable

$$Z = \frac{\bar{X} - \mu}{\sigma/\sqrt{n}} = \frac{\sqrt{n}(\bar{X} - \mu)}{\sigma} \quad (207.9)$$

has approximately an  $\mathcal{N}(0, 1)$  distribution. More precisely,

$$P[Z \leq z] \rightarrow \Phi(z) \quad \text{for every fixed } z \text{ as } n \rightarrow \infty \quad (207.10)$$

## 207.3 Normal Distribution-Related Sampling Distributions

---

### One-Sample Case

Additional results exist when the observations come from a normal population. If  $X_1, X_2, \dots, X_n$  represent a random sample of size  $n$  from an  $\mathcal{N}(\mu, \sigma^2)$  population, then the following sampling distributions are useful.

**Fact 1.**

For every fixed  $n$ , the distribution of  $Z$  given in Eq.(207.9) has exactly an  $\mathcal{N}(0, 1)$  distribution.

**Fact 2.**

The distribution of the statistic  $T = \sqrt{n}(\bar{X} - \mu)/S$ , where  $S = \sqrt{S^2}$  is the sample standard deviation, is called a Student's  $t$  distribution with  $\nu = n - 1$  degrees of freedom; in symbols,  $t(n - 1)$ .

This distribution is useful for making inference on  $\mu$  when  $\sigma^2$  is unknown. A table of the percentiles can be found in most statistics textbooks.

**Fact 3.**

The distribution of the statistic  $W = (n - 1)S^2/\sigma^2$  is called a chi-squared distribution with  $\nu = n - 1$  degrees of freedom; in symbols,  $\chi^2(\nu)$ .

Such a distribution is useful in making inference on  $\sigma^2$ . A table of the percentiles can also be found in most statistics books.

### Two-Sample Case

In certain applications, we may be interested in the comparisons of two different treatments. Suppose that independent samples from treatments  $T_1$  and  $T_2$  are to be observed as shown in [Table 207.1](#). The difference of the population means  $(\mu_1 - \mu_2)$  and the ratio of the population variances can be estimated, respectively, by  $(\bar{X}_1 - \bar{X}_2)$  and  $S_1^2/S_2^2$ . The following facts summarize the distributions of these statistics.

**Table 207.1** Summary of Data for a Two-Sample Problem

Treatment	Observations	Distribution	Sample Size	Sample Mean	Sample Variance
$T_1$	$X_{11}, X_{12}, \dots, X_{1n_1}$	$\mathcal{N}(\mu_1, \sigma_1^2)$	$n_1$	$\bar{X}_1$	$S_1^2$
$T_2$	$X_{21}, X_{22}, \dots, X_{2n_2}$	$\mathcal{N}(\mu_2, \sigma_2^2)$	$n_2$	$\bar{X}_2$	$S_2^2$

**Fact 4.**

Under the assumption of normality,  $(\bar{X}_1 - \bar{X}_2)$  has an  $\mathcal{N}(\mu_1 - \mu_2, (\sigma_1^2/n_1) + (\sigma_2^2/n_2))$  distribution; or equivalently, for all  $n_1$  and  $n_2$ , the statistic

$$Z = [(\bar{X}_1 - \bar{X}_2) - (\mu_1 - \mu_2)]/(\sigma_1^2/n_1 + \sigma_2^2/n_2)^{1/2} \quad (207.11)$$

has an  $\mathcal{N}(0, 1)$  distribution.

**Fact 5.**

When  $\sigma_1^2 = \sigma_2^2 \equiv \sigma^2$ , the common population variance is estimated by

$$S_p^2 = (n_1 + n_2 - 2)^{-1} [(n_1 - 1)S_1^2 + (n_2 - 1)S_2^2] \quad (207.12)$$

and  $(n_1 + n_2 - 2)S_p^2/\sigma^2$  has a  $\chi^2(n_1 + n_2 - 2)$  distribution.

**Fact 6.**

When  $\sigma_1^2 = \sigma_2^2$ , the statistic

$$T = [(\bar{X}_1 - \bar{X}_2) - (\mu_1 - \mu_2)]/S_p(1/n_1 + 1/n_2)^{1/2} \quad (207.13)$$

has a  $t(n_1 + n_2 - 2)$  distribution, where  $S_p = \sqrt{S_p^2}$ .

**Fact 7.**

The distribution of  $F = (S_1^2/\sigma_1^2)/(S_2^2/\sigma_2^2)$  is called an  $F$  distribution with degrees of freedom  $(n_1 - 1, n_2 - 1)$ ; in symbols,  $F(n_1 - 1, n_2 - 1)$ .

The percentiles of this distribution have also been tabulated and can be found in statistics books.

The distributions listed above (normal, Student's  $t$ , chi-squared, and  $F$ ) form an important part of classical statistical inference theory, and they are developed under the assumption that the observations follow a normal distribution. When the distribution of the population is not normal and inference on the population means is to be made, we conclude that (i) if the sample sizes  $n_1$  and  $n_2$  are large, then the statistic  $Z$  in Eq. (207.11) has an approximate  $\mathcal{N}(0, 1)$  distribution, (ii) in the small-sample case, the exact distribution of  $\bar{X}$  [of  $(\bar{X}_1 - \bar{X}_2)$ ] depends on the population p.d.f. There are several analytical methods for obtaining it, and those methods can be found in statistics textbooks.

## 207.4 Confidence Intervals

---

A method for estimating the population parameters based on the sample mean(s) and sample variance(s) involves the confidence intervals for the parameters.

## One-Sample Case

### Confidence Interval for $\mu$ When $\sigma^2$ Is Known

Consider the situation in which a random sample of size  $n$  is taken from an  $\mathcal{N}(\mu, \sigma^2)$  population and  $\sigma^2$  is known. An interval,  $I_1$ , of the form  $I_1 = (\bar{X} - d, \bar{X} + d)$  (with width  $2d$ ) is to be constructed as a *confidence interval* for  $\mu$ . If we make the assertion that  $\mu$  is in this interval (i.e.,  $\mu$  is bounded below by  $\bar{X} - d$ , and bounded above by  $\bar{X} + d$ ), then sometimes this assertion is correct and sometimes it is wrong, depending on the value of  $\bar{X}$  in a given experiment. If for a fixed  $\alpha$  value we would like to have a confidence probability (called confidence coefficient) such that

$$P[\mu \in I_1] = P[\bar{X} - d < \mu < \bar{X} + d] = 1 - \alpha \quad (207.14)$$

then we need to choose the value of  $d$  to satisfy  $d = z_{\alpha/2} \sigma / \sqrt{n}$ ; that is,

$$I_1 = \left( \bar{X} - z_{\alpha/2} \frac{\sigma}{\sqrt{n}}, \bar{X} + z_{\alpha/2} \frac{\sigma}{\sqrt{n}} \right) \quad (207.15)$$

where  $z_{\alpha/2}$  is the  $(1 - \alpha/2)$  th percentile of the  $\mathcal{N}(0, 1)$  distribution such that  $\Phi(z_{\alpha/2}) = 1 - \alpha/2$ . To see this, we note that, from the sampling distribution of  $\bar{X}$  (Fact 1), we have

$$\begin{aligned} P \left[ \bar{X} - z_{\alpha/2} \frac{\sigma}{\sqrt{n}} < \mu < \bar{X} + z_{\alpha/2} \frac{\sigma}{\sqrt{n}} \right] &= P \left[ \frac{|\bar{X} - \mu|}{\sigma / \sqrt{n}} \leq z_{\alpha/2} \right] \\ &= \Phi(z_{\alpha/2}) - \Phi(-z_{\alpha/2}) = 1 - \alpha. \end{aligned} \quad (207.16)$$

We further note that, even when the original population is not normal, by Theorem 2 the confidence probability is approximately  $(1 - \alpha)$  when the sample size is reasonably large.

### Confidence Interval for $\mu$ When $\sigma^2$ Is Unknown

Assume that the observations are from an  $\mathcal{N}(\mu, \sigma^2)$  population. When  $\sigma^2$  is unknown, by Fact 2 and a similar argument we see that

$$I_2 = \left( \bar{X} - t_{\alpha/2}(n-1) \frac{S}{\sqrt{n}}, \bar{X} + t_{\alpha/2}(n-1) \frac{S}{\sqrt{n}} \right) \quad (207.17)$$

is a confidence interval for  $\mu$  with confidence probability  $1 - \alpha$ , where  $t_{\alpha/2}(n-1)$  is the  $(1 - \alpha/2)$  th percentile of the  $t(n-1)$  distribution.

### Confidence Interval for $\sigma^2$

If, under the same assumption of normality, a confidence interval for  $\sigma^2$  is needed when  $\mu$  is unknown, then

$$I_3 = ((n-1)S^2/\chi_{1-\alpha/2}^2(n-1), (n-1)S^2/\chi_{\alpha/2}^2(n-1)) \quad (207.18)$$

has a confidence probability  $1 - \alpha$ , when  $\chi_{1-\alpha/2}^2(n-1)$  and  $\chi_{\alpha/2}^2(n-1)$  are the  $(\alpha/2)$  th and  $(1 - \alpha/2)$  th percentiles, respectively, of the  $\chi^2(n-1)$  distribution.

## Two-Sample Case

### Confidence Intervals for $\mu_1 - \mu_2$ When $\sigma_1^2$ and $\sigma_2^2$ Are Known

Consider an experiment that involves the comparison of two treatments,  $T_1$  and  $T_2$ , as indicated in [Table 207.1](#). If a confidence interval for  $\delta = \mu_1 - \mu_2$  is needed when  $\sigma_1^2$  and  $\sigma_2^2$  are known then, by Fact 4 and a similar argument, the confidence interval

$$I_4 = \left( (\bar{X}_1 - \bar{X}_2) - z_{\alpha/2} \sqrt{\sigma_1^2/n_1 + \sigma_2^2/n_2}, (\bar{X}_1 - \bar{X}_2) + z_{\alpha/2} \sqrt{\sigma_1^2/n_1 + \sigma_2^2/n_2} \right) \quad (207.19)$$

has a confidence probability  $1 - \alpha$ .

### Confidence Interval for $\mu_1 - \mu_2$ When $\sigma_1^2$ and $\sigma_2^2$ Are Unknown but Equal

Under the additional assumption that  $\sigma_1^2 = \sigma_2^2$  but the common variance is unknown, then by Fact 6 the confidence interval

$$I_5 = [(\bar{X}_1 - \bar{X}_2) - d, (\bar{X}_1 - \bar{X}_2) + d] \quad (207.20)$$

has a confidence probability  $1 - \alpha$ , where

$$d = t_{\alpha/2}(n_1 + n_2 - 2)S_p(1/n_1 + 1/n_2)^{1/2} \quad (207.21)$$

### Confidence Interval for $\sigma_1^2/\sigma_2^2$

A confidence interval for the ratio of the variances  $\sigma_2^2/\sigma_1^2$  can be obtained from the  $F$  distribution (see Fact 7), and the confidence interval

$$I_6 = \left( F_{1-\alpha/2}(n_1 - 1, n_2 - 1) \frac{S_2^2}{S_1^2}, F_{\alpha/2}(n_1 - 1, n_2 - 1) \frac{S_2^2}{S_1^2} \right) \quad (207.22)$$

has a confidence probability  $1 - \alpha$ , where  $F_{1-\alpha/2}(n_1 - 1, n_2 - 1)$  and  $F_{\alpha/2}(n_1 - 1, n_2 - 1)$  are, respectively, the  $(\alpha/2)$  th and  $(1 - \alpha/2)$  th percentiles of the  $F(n_1 - 1, n_2 - 1)$  distribution.

## 207.5 Testing Statistical Hypotheses

---

A statistical hypothesis concerns a statement or assertion about the true value of the parameter in a given distribution. In the two-hypothesis problems, we deal with a null hypothesis and an alternative hypothesis, denoted by  $H_0$  and  $H_1$ , respectively. A decision is to be made, based on the data of the experiment, to either accept  $H_0$  (hence reject  $H_1$ ) or reject  $H_0$  (hence accept  $H_1$ ). In such a two-action problem, there are two types of errors we may commit: the type I error is to reject  $H_0$  when it is true, and the type II error is to accept  $H_0$  when it is false. As a standard practice, we do not reject  $H_0$  unless there is significant evidence indicating that it may be false (in doing so, the burden of proof that  $H_0$  is false is on the experimenter). Thus, we usually choose a small fixed number,  $\alpha$  (such as 0.05 or 0.01), such that the probability of committing a type I error is at most  $\alpha$ . With such a given  $\alpha$ , we can then determine the region in the data space for the rejection of  $H_0$  (called the critical region).

### One-Sample Case

Suppose that  $X_1, X_2, \dots, X_n$  represent a random sample of size  $n$  from an  $\mathcal{N}(\mu, \sigma^2)$  population, and  $\bar{X}$  and  $S^2$  are, respectively, the sample mean and sample variance.

#### Test for Mean

In testing

$$H_0 : \mu = \mu_0 \quad \text{vs.} \quad H_1 : \mu = \mu_1 (\mu_1 > \mu_0) \text{ or } H_1 : \mu > \mu_0$$

when  $\sigma^2$  is known, we reject  $H_0$  when  $\bar{X}$  is large. To determine the cut-off point, we note that (by Fact 1) the statistic  $Z_0 = (\bar{X} - \mu_0)/(\sigma/\sqrt{n})$  has an  $\mathcal{N}(0, 1)$  distribution under  $H_0$ . Thus if we decide to reject  $H_0$  when  $Z_0 > z_\alpha$ , then the probability of committing a type I error is  $\alpha$ . As a consequence, we apply the decision rule

$$d_1: \text{reject } H_0 \text{ if and only if } \bar{X} > \mu_0 + z_\alpha \frac{\sigma}{\sqrt{n}}.$$

Similarly, from the distribution of  $Z_0$  under  $H_0$ , we can obtain the critical region for the other types of hypotheses. When  $\sigma^2$  is unknown, then by Fact 2,  $T_0 = \sqrt{n}(\bar{X} - \mu_0)/S$  has a  $t(n-1)$  distribution under  $H_0$ . Thus, the corresponding tests can be obtained by substituting  $t_\alpha(n-1)$  for  $z_\alpha$  and  $S$  for  $\sigma$ . The tests for the various one-sided and two-sided hypotheses are summarized in [Table 207.2](#). For each set of hypotheses, the critical region given on the first line is for the case when  $\sigma^2$  is known, and that given on the second line is for the case when  $\sigma^2$  is unknown. Furthermore,  $t_\alpha$  and  $t_{\alpha/2}$  stand for  $t_\alpha(n-1)$  and  $t_{\alpha/2}(n-1)$ , respectively.

**Table 207.2** One-Sample Tests for Mean

Null Hypothesis $H_0$	Alternative Hypothesis $H_1$	Critical Region
$\mu = \mu_0$ or $\mu \leq \mu_0$	$\mu = \mu_1 > \mu_0$ or $\mu > \mu_0$	$\bar{X} > \mu_0 + z_\alpha \frac{\sigma}{\sqrt{n}}$ $\bar{X} > \mu_0 + t_\alpha \frac{S}{\sqrt{n}}$
$\mu = \mu_0$ or $\mu \geq \mu_0$	$\mu = \mu_1 < \mu_0$ or $\mu < \mu_0$	$\bar{X} < \mu_0 - z_\alpha \frac{\sigma}{\sqrt{n}}$ $\bar{X} < \mu_0 - t_\alpha \frac{S}{\sqrt{n}}$
$\mu = \mu_0$	$\mu \neq \mu_0$	$ \bar{X} - \mu_0  > z_{\alpha/2} \frac{\sigma}{\sqrt{n}}$ $ \bar{X} - \mu_0  > t_{\alpha/2} \frac{S}{\sqrt{n}}$

**Test for Variance**

In testing hypotheses concerning the variance  $\sigma^2$  of a normal distribution, we use Fact 3 to assert that, under  $H_0 : \sigma^2 = \sigma_0^2$ , the distribution of  $w_0 = (n-1)S^2/\sigma_0^2$  is  $\chi^2(n-1)$ . The corresponding tests and critical regions are summarized in Table 207.3 ( $\chi_\alpha^2$  and  $\chi_{\alpha/2}^2$  stand for  $\chi_\alpha^2(n-1)$  and  $\chi_{\alpha/2}^2(n-1)$ , respectively).

**Table 207.3** One-Sample Tests for Variance

Null Hypothesis $H_0$	Alternative Hypothesis $H_1$	Critical Region
$\sigma^2 = \sigma_0^2$ or $\sigma^2 \leq \sigma_0^2$	$\sigma^2 = \sigma_1^2 > \sigma_0^2$ or $\sigma^2 > \sigma_0^2$	$(S^2/\sigma_0^2) > \frac{1}{n-1} \chi_\alpha^2$
$\sigma^2 = \sigma_0^2$ or $\sigma^2 \geq \sigma_0^2$	$\sigma^2 = \sigma_1^2 < \sigma_0^2$ or $\sigma^2 < \sigma_0^2$	$(S^2/\sigma_0^2) < \frac{1}{n-1} \chi_{1-\alpha}^2$
$\sigma^2 = \sigma_0^2$	$\sigma^2 \neq \sigma_0^2$	$(S^2/\sigma_0^2) > \frac{1}{n-1} \chi_{\alpha/2}^2$ or $(S^2/\sigma_0^2) < \frac{1}{n-1} \chi_{1-\alpha/2}^2$

**Two-Sample Case**

In comparing the means and variances of two normal populations, we once again refer to Table 207.1 for notation and assumptions.

**Test for Difference of Two Means**

Let  $\delta = \mu_1 - \mu_2$  be the difference of the two population means. In testing  $H_0 : \delta = \delta_0$  versus a one-sided or two-sided alternative hypothesis, we note that, for

$$\tau = (\sigma_1^2/n_1 + \sigma_2^2/n_2)^{1/2} \quad (207.23)$$

and

$$v = S_p(1/n_1 + 1/n_2)^{1/2} \quad (207.24)$$

$Z_0 = [(\bar{X}_1 - \bar{X}_2) - \delta_0]/\tau$  has an  $\mathcal{N}(0, 1)$  distribution under  $H_0$ , and  $T_0 = [(\bar{X}_1 - \bar{X}_2) - \delta_0]/v$

has a  $t(n_1 + n_2 - 2)$  distribution under  $H_0$  when  $\sigma_1^2 = \sigma_2^2$ . Using these results, the corresponding critical regions for one-sided and two-sided tests can be obtained, and they are listed in [Table 207.4](#). Note that, as in the one-sample case, the critical region given on the first line for each set of hypotheses is for the case of known variances, and that given on the second line is for the case in which the variances are equal but unknown. Further,  $t_\alpha$  and  $t_{\alpha/2}$  stand for  $t_\alpha(n_1 + n_2 - 2)$  and  $t_{\alpha/2}(n_1 + n_2 - 2)$ , respectively.

**Table 207.4** Two-Sample Tests for Difference of Two Means

Null Hypothesis $H_0$	Alternative Hypothesis $H_1$	Critical Region
$\delta = \delta_0$ or $\delta \leq \delta_0$	$\delta = \delta_1 > \delta_0$ or $\delta > \delta_0$	$(\bar{X}_1 - \bar{X}_2) > \delta_0 + z_\alpha \tau$ $(\bar{X}_1 - \bar{X}_2) > \delta_0 + t_\alpha v$
$\delta = \delta_0$ or $\delta \geq \delta_0$	$\delta = \delta_1 < \delta_0$ or $\delta < \delta_0$	$(\bar{X}_1 - \bar{X}_2) < \delta_0 - z_\alpha \tau$ $(\bar{X}_1 - \bar{X}_2) < \delta_0 - t_\alpha v$
$\delta = \delta_0$	$\delta \neq \delta_0$	$ (\bar{X}_1 - \bar{X}_2) - \delta_0  > z_{\alpha/2} \tau$ $ (\bar{X}_1 - \bar{X}_2) - \delta_0  > t_{\alpha/2} v$

## 207.6 A Numerical Example

In the following, we provide a numerical example for illustrating the construction of confidence intervals and hypothesis-testing procedures. The example is given along the line of applications in Wadsworth [1990, p. 4.21] with artificial data.

Suppose that two processes,  $T_1$  and  $T_2$ , for manufacturing steel pins are in operation, and that a random sample of four pins (of five pins) was taken from the process  $T_1$  (the process  $T_2$ ) with the following results (in units of inches):

$$T_1: 0.7608, 0.7596, 0.7622, 0.7638$$

$$T_2: 0.7546, 0.7561, 0.7526, 0.7572, 0.7565$$

Simple calculation shows that the observed values of sample means, sample variances, and sample standard deviations are

$$\bar{X}_1 = 0.7616, \quad S_1^2 = 3.178914 \cdot 10^{-6}, \quad S_1 = 1.7830 \cdot 10^{-3}$$

$$\bar{X}_2 = 0.7554, \quad S_2^2 = 3.516674 \cdot 10^{-6}, \quad S_2 = 1.8753 \cdot 10^{-3}$$

## One-Sample Case

Let us first consider confidence intervals for the parameters of the first process,  $T_1$ , only.

1. Assume that, based on previous knowledge on processes of this type, the variance is known

to be  $\sigma_1^2 = 1.80^2 \cdot 10^{-6}$  ( $\sigma_1 = 0.0018$ ). Then, from the normal table [Ross, 1987, p. 482], we have  $z_{0.025} = 1.96$ . Thus, a 95% confidence interval for  $\mu_1$  is

$$(0.7616 - 1.96 \times 0.0018/\sqrt{4}, 0.7616 + 1.96 \times 0.0018/\sqrt{4})$$

or (0.7598, 0.7634) (after rounding off to the fourth decimal place).

2. If  $\sigma_1^2$  is unknown and a 95% confidence interval for  $\mu_1$  is needed, then, for  $t_{0.025}(3) = 3.182$  [Ross, 1987, p. 484], the confidence interval is

$$(0.7616 - 3.182 \times 0.001783/\sqrt{4}, 0.7616 + 3.182 \times 0.001783/\sqrt{4})$$

or (0.7588, 0.7644).

3. From the chi-squared table with  $4-1 = 3$  degrees of freedom, we have [Ross, 1987, p. 483]  $\chi_{0.975}^2 = 0.216$ ,  $\chi_{0.025}^2 = 9.348$ . Thus, a 95% confidence interval for  $\sigma_1^2$  is  $(3 \times 3.178914 \cdot 10^{-6}/9.348, 3.178914 \cdot 10^{-6}/0.216)$ , or  $(1.0202 \cdot 10^{-6}, 44.15158 \cdot 10^{-6})$ .
4. In testing the hypotheses

$$H_0 : \mu_1 = 0.76 \quad \text{vs.} \quad H_1 : \mu_1 > 0.76$$

with  $\alpha = 0.01$  when  $\sigma_1^2$  is unknown, the critical region is

$\bar{x}_1 > 0.76 + 4.541 \times 0.001783/\sqrt{4} = 0.7640$ . Because the observed value of  $\bar{x}_1$  is 0.7616,  $H_0$  is accepted. That is, we assert that there is no significant evidence to call for the rejection of  $H_0$ .

## Two-Sample Case

If we assume that the two populations have a common unknown variance, we can use the Student's  $t$  distribution (with degree of freedom  $\nu = 4 + 5 - 2 = 7$ ) to obtain confidence intervals and to test hypotheses for  $\mu_1 - \mu_2$ . We first note that the data given above yield

$$\begin{aligned} S_p^2 &= \frac{1}{7}(3 \times 3.178414 + 4 \times 3.516674) \cdot 10^{-6} \\ &= 3.371920 \cdot 10^{-6}, \\ S_p &= 1.836279 \cdot 10^{-3}, \quad v = S_p \sqrt{1/4 + 1/5} = 1.231813 \cdot 10^{-3} \end{aligned}$$

and  $\bar{X}_1 - \bar{X}_2 = 0.0062$ .

1. A 98% confidence interval for  $\mu_1 - \mu_2$  is  $(0.0062 - 2.998 \cdot v, 0.0062 + 2.998v)$  or (0.0025, 0.0099).
2. In testing the hypotheses  $H_0 : \mu_1 = \mu_2$  (i.e.,  $\mu_1 - \mu_2 = 0$ ) vs.  $H_1 : \mu_1 > \mu_2$  with  $\alpha = 0.05$ , the critical region is  $(X_1 - X_2) > 1.895v = 2.3344 \cdot 10^{-3}$ . Thus,  $H_0$  is rejected (i.e., we

- conclude that there is significant evidence to indicate that  $\mu_1 > \mu_2$  may be true).
3. In testing the hypotheses  $H_0 : \mu_1 = \mu_2$  vs  $H_1 : \mu_1 \neq \mu_2$  with  $\alpha = 0.02$ , the critical region is  $|X_1 - X_2| > 2.998v = 3.6930 \cdot 10^{-3}$ . Thus,  $H_0$  is rejected. We note this conclusion is consistent with the result that, with confidence probability  $1 - \alpha = 0.98$ , the confidence interval for  $(\mu_1 - \mu_2)$  does not contain the origin.

## Further Information

Other important topics in engineering probability and statistics include sampling inspection and quality (process) control, reliability, regression analysis and prediction, design of engineering experiments, and analysis of variance. Due to space limitations, these topics are not treated in this chapter. The reader is referred to textbooks in this area for further information. There are many well-written books that cover most of these topics. The short list of references above consists of a small sample of them.

### 208.1 Linear Programming

---

Let  $\mathbf{A}$  be an  $m \times n$  matrix,  $\mathbf{b}$  a column vector with  $m$  components, and  $\mathbf{c}$  a column vector with  $n$  components. Suppose  $m < n$ , and assume the rank of  $\mathbf{A}$  is  $m$ . The standard linear programming problem is to find, among all nonnegative solutions of  $\mathbf{Ax} = \mathbf{b}$ , one that minimizes

$$\mathbf{c}^T \mathbf{x} = c_1 x_1 + c_2 x_2 + \cdots + c_n x_n$$

This problem is called a *linear* program. Each solution of the system  $\mathbf{Ax} = \mathbf{b}$  is called a *feasible* solution, and the *feasible set* is the collection of all *feasible solutions*. The function  $\mathbf{c}^T \mathbf{x} = c_1 x_1 + c_2 x_2 + \cdots + c_n x_n$  is the *cost function*, or the *objective function*. A solution to the linear program is called an *optimal feasible solution*.

Let  $\mathbf{B}$  be an  $m \times m$  submatrix of  $\mathbf{A}$  made up of  $m$  linearly independent columns of  $\mathbf{A}$ , and let  $\mathbf{C}$  be the  $m \times (n - m)$  matrix made up of the remaining columns of  $\mathbf{A}$ . Let  $\mathbf{x}_B$  be the vector consisting of the components of  $\mathbf{x}$  corresponding to the columns of  $\mathbf{A}$  that make up  $\mathbf{B}$ , and let  $\mathbf{x}_C$  be the vector of the remaining components of  $\mathbf{x}$ , that is, the components of  $\mathbf{x}$  that correspond to the columns of  $\mathbf{C}$ . Then the equation  $\mathbf{Ax} = \mathbf{b}$  may be written  $\mathbf{Bx}_B + \mathbf{Cx}_C = \mathbf{b}$ . A solution of  $\mathbf{Bx}_B = \mathbf{b}$  together with  $\mathbf{x}_C = \mathbf{0}$  gives a solution  $\mathbf{x}$  of the system  $\mathbf{Ax} = \mathbf{b}$ . Such a solution is called a *basic solution*, and if it is, in addition, nonnegative, it is a *basic feasible solution*. If it is also optimal, it is an *optimal basic feasible solution*. The components of a basic solution are called *basic variables*.

The Fundamental Theorem of Linear Programming says that if there is a feasible solution, there is a basic feasible solution, and if there is an optimal feasible solution, there is an optimal basic feasible solution. The linear programming problem is thus reduced to searching among the set of basic solutions for an optimal solution. This set is, of course, finite, containing as many as  $n!/[m!(n - m)!]$  points. In practice, this will be a very large number, making it imperative that one use some efficient search procedure in seeking an optimal solution. The most important of

such procedures is the *simplex method*, details of which may be found in the references.

The problem of finding a solution of  $Ax \leq b$  that minimizes  $c^T x$  can be reduced to the standard problem by appending to the vector  $x$  an additional  $m$  nonnegative components, called *slack variables*. The vector  $x$  is replaced by  $z$ , where  $z^T = [x_1 x_2 \dots x_n \ s_1 s_2 \dots s_m]$ , and the matrix  $A$  is replaced by  $B = [A \ I]$ , where  $I$  is the  $m \times m$  identity matrix. The equation  $Ax = b$  is thus replaced by  $Bz = Ax + s = b$ , where  $s^T = [s_1 s_2 \dots s_m]$ . Similarly, if inequalities are reversed so that we have  $Ax \geq b$ , we simply append  $-s$  to the vector  $x$ . In this case, the additional variables are called *surplus variables*.

Associated with every linear programming problem is a corresponding dual problem. If the *primal* problem is to minimize  $c^T x$  subject to  $Ax \geq b$ , and  $x \geq 0$ , the corresponding *dual* problem is to maximize  $y^T b$  subject to  $y^T A \leq c^T$ . If either the primal problem or the dual problem has an optimal solution, so also does the other. Moreover, if  $x_p$  is an optimal solution for the primal problem and  $y_d$  is an optimal solution for the corresponding dual problem,  $c^T x_p = y_d^T b$ .

## 208.2 Unconstrained Nonlinear Programming

---

The problem of minimizing or maximizing a sufficiently smooth nonlinear function  $f(x)$  of  $n$  variables,  $x^T = [x_1 x_2 \dots x_n]$ , with no restrictions on  $x$  is essentially an ordinary problem in calculus. At a minimizer or maximizer  $x^*$ , it must be true that the gradient of  $f$  vanishes:

$$\nabla f(x^*) = 0$$

Thus  $x^*$  will be in the set of all solutions of this system of  $n$  generally nonlinear equations. The solution of the system can be, of course, a nontrivial undertaking. There are many recipes for solving systems of nonlinear equations. A method specifically designed for minimizing  $f$  is the *method of steepest descent*. It is an old and honorable algorithm, and the one on which most other more complicated algorithms for unconstrained optimization are based. The method is based on the fact that at any point  $x$ , the direction of maximum decrease of  $f$  is in the direction of  $-\nabla f(x)$ . The algorithm searches in this direction for a minimum, recomputes  $-\nabla f(x)$  at this point, and continues iteratively. Explicitly:

1. Choose an initial point  $x_0$ .
2. Assume  $x_k$  has been computed; then compute  $y_k = \nabla f(x_k)$ , and let  $t_k \geq 0$  be a local minimum of  $g(t) = f(x_k - ty_k)$ . Then  $x_{k+1} = x_k - t_k y_k$ .
3. Replace  $k$  by  $k + 1$ , and repeat step 2 until  $t_k$  is small enough.

Under reasonably general conditions, the sequence  $(x_k)$  converges to a minimum of  $f$ .

## 208.3 Constrained Nonlinear Programming

---

The problem of finding the maximum or minimum of a function  $f(x)$  of  $n$  variables subject to the constraints

$$\mathbf{a}(\mathbf{x}) = \begin{bmatrix} a_1(x_1, x_2, \dots, x_n) \\ a_2(x_1, x_2, \dots, x_n) \\ \vdots \\ a_m(x_1, x_2, \dots, x_n) \end{bmatrix} = \begin{bmatrix} b_1 \\ b \\ \vdots \\ b_m \end{bmatrix} = \mathbf{b}$$

is made into an unconstrained problem by introducing the new function  $L(\mathbf{x})$  :

$$L(\mathbf{x}) = f(\mathbf{x}) + \mathbf{z}^T \mathbf{a}(\mathbf{x})$$

where  $\mathbf{z}^T = [\lambda_1 \lambda_2 \dots \lambda_m]$  is the vector of *Lagrange multipliers*. Now the requirement that  $\nabla L(\mathbf{x}) = 0$  , together with the constraints  $\mathbf{a}(\mathbf{x}) = \mathbf{b}$  , give a system of  $n + m$  equations

$$\begin{aligned} \nabla f(\mathbf{x}) + \mathbf{z}^T \nabla \mathbf{a}(\mathbf{x}) &= 0 \\ \mathbf{a}(\mathbf{x}) &= \mathbf{b} \end{aligned}$$

for the  $n + m$  unknowns  $x_1, x_2, \dots, x_n, \lambda_1, \lambda_2, \dots, \lambda_m$  that must be satisfied by the minimizer (or maximizer)  $\mathbf{x}$  .

The problem of inequality constraints is significantly more complicated in the nonlinear case than in the linear case. Consider the problem of minimizing  $f(\mathbf{x})$  subject to  $m$  equality constraints  $\mathbf{a}(\mathbf{x}) = \mathbf{b}$  , and  $p$  inequality constraints  $\mathbf{c}(\mathbf{x}) \leq \mathbf{d}$  [thus  $\mathbf{a}(\mathbf{x})$  and  $\mathbf{b}$  are vectors of  $m$  components, and  $\mathbf{c}(\mathbf{x})$  and  $\mathbf{d}$  are vectors of  $p$  components]. A point  $\mathbf{x}^*$  that satisfies the constraints is a *regular point* if the collection

$$\{\nabla a_1(\mathbf{x}^*), \nabla a_2(\mathbf{x}^*), \dots, \nabla a_m(\mathbf{x}^*)\} \cup \{\nabla c_j(\mathbf{x}^*) : j \in J\}$$

where

$$J = \{j : c_j(\mathbf{x}^*) = d_j\}$$

is linearly independent. If  $\mathbf{x}^*$  is a local minimum for the constrained problem and if it is a regular point, there is a vector  $\mathbf{z}$  with  $m$  components and a vector  $\mathbf{w} \geq 0$  with  $p$  components such that

$$\begin{aligned} \nabla f(\mathbf{x}^*) + \mathbf{z}^T \nabla \mathbf{a}(\mathbf{x}^*) + \mathbf{w}^T \nabla \mathbf{c}(\mathbf{x}^*) &= 0 \\ \mathbf{w}^T (\mathbf{c}(\mathbf{x}^*) - \mathbf{d}) &= 0 \end{aligned}$$

These are the *Kuhn-Tucker conditions*. Note that in order to solve these equations, one needs to know for which  $j$  it is true that  $c_j(\mathbf{x}^*) = 0$  . (Such a constraint is said to be *active*.)

**William F. Ames***Georgia Institute of Technology***Introduction**

Since many mathematical models of physical phenomena are not solvable by available mathematical methods one must often resort to approximate or numerical methods. These

procedures do not yield exact results in the mathematical sense. This inexact nature of numerical results means we must pay attention to the errors. The two errors that concern us here are *round-off errors* and *truncation errors*.

Round-off errors arise as a consequence of using a number specified by  $m$  correct digits to approximate a number which requires more than  $m$  digits for its exact specification. For example, using 3.14159 to approximate the irrational number  $\pi$ . Such errors may be especially serious in matrix inversion or in any area where a very large number of numerical operations are required. Some attempts at handling these errors are called *enclosure methods* [Adams and Kulisch, 1993].

Truncation errors arise from the substitution of a finite number of steps for an infinite sequence of steps (usually an iteration) which would yield the exact result. For example, the iteration  $y_n(x) = 1 + \int_0^x xty_{n-1}(t)dt$ ,  $y(0) = 1$  is only carried out for a *few steps*, but it converges in *infinitely* many steps.

The study of some errors in a computation is related to the theory of probability. In what follows, a relation for the error will be given in certain instances.

## 209.1 Linear Algebra Equations

---

A problem often met is the determination of the solution vector  $u = (u_1, u_2, \dots, u_n)^T$  for the set of linear equations  $Au = v$  where  $A$  is the  $n \times n$  square matrix with coefficients  $a_{ij}$  ( $i, j = 1, \dots, n$ ) and  $v = (v_1, \dots, v_n)^T$ , and  $i$  denotes the row index and  $j$  the column index.

There are many numerical methods for finding the solution,  $u$ , of  $Au = v$ . The direct inversion of  $A$  is usually too expensive and is not often carried out unless it is needed elsewhere. We shall only list a few methods. One can check the literature for the many methods and computer software available. Some of the software is listed in the References section at the end of this chapter. The methods are usually subdivided into *direct* (once through) or *iterative* (repeated) procedures.

In what follows, it will often be convenient to partition the matrix  $A$  into the form  $A = U + D + L$ , where  $U$ ,  $D$ , and  $L$  are matrices having the same elements as  $A$ , respectively, above the main diagonal, on the main diagonal, and below the main diagonal, and zeros elsewhere. Thus,

$$U = \begin{bmatrix} 0 & a_{12} & & \cdots & a_{1n} \\ 0 & 0 & a_{23} & \cdots & a_{2n} \\ \vdots & \cdots & & \cdots & \\ 0 & 0 & \cdots & \cdots & 0 \end{bmatrix}$$

We also assume the  $u_j$ s are not all zero and  $\det A \neq 0$  so the solution is unique.

## Direct Methods

### Gauss Reduction

This classical method has spawned many variations. It consists of dividing the first equation by  $a_{11}$  (if  $a_{11} = 0$ , reorder the equations to find an  $a_{11} \neq 0$ ) and using the result to eliminate the terms in  $u_1$

from each of the succeeding equations. Next, the modified second equation is divided by  $a'_{22}$  (if  $a'_{22} = 0$ , a reordering of the modified equations may be necessary) and the resulting equation is used to eliminate all terms in  $u_2$  in the succeeding modified equations. This elimination is done  $n$  times resulting in a triangular system:

$$\begin{array}{ccccccc} u_1 + a'_{12}u_2 + \cdots & + a'_{1n}u_n & = & v'_1 \\ 0 & + u_2 & + \cdots & + a'_{2n}u_n & = & v'_2 \\ & & \cdots & & & \\ 0 & + \cdots & + u_{n-1} & + a'_{n-1,n}u_n & = & v'_{n-1} \\ & & & & u_n & = & v'_n \end{array}$$

where  $a'_{ij}$  and  $v'_j$  represent the specific numerical values obtained by this process. The solution is obtained by working backward from the last equation. Various modifications, such as the Gauss-Jordan reduction, the Gauss-Doolittle reduction, and the Crout reduction, are described in the classical reference authored by Bodewig [1956]. Direct methods prove very useful for sparse matrices and banded matrices that often arise in numerical calculation for differential equations. Many of these are available in computer packages such as IMSL, Maple, Matlab, and Mathematica.

### The Tridiagonal Algorithm

When the linear equations are tridiagonal, the system

$$\begin{array}{l} b_1 u_1 + c_1 u_2 = d_1 \\ a_i u_{i-1} + b_i u_i + c_i u_{i+1} = d_i \\ a_n u_{n-1} + b_n u_n = d_n, \quad i = 2, 3, \dots, n-1 \end{array}$$

can be solved explicitly for the unknowns, thereby eliminating any matrix operations.

The Gaussian elimination process transforms the system into a simpler one of *upper bidiagonal* form. We designate the coefficients of this new system by  $a'_i$ ,  $b'_i$ ,  $c'_i$ , and  $d'_i$ , and we note that

$$\begin{array}{l} a'_i = 0, \quad i = 2, 3, \dots, n \\ b'_i = 1, \quad i = 1, 2, \dots, n \end{array}$$

The coefficients  $c'_i$  and  $d'_i$  are calculated successively from the relations

$$c'_1 = \frac{c_1}{b_1} \quad d'_1 = \frac{d_1}{b_1}$$

$$c'_{i+1} = \frac{c_{i+1}}{b_{i+1} - a_{i+1} c'_i}$$

$$d'_{i+1} = \frac{d_{i+1} - a_{i+1} d'_i}{b_{i+1} - a_{i+1} c'_i}, \quad i = 1, 2, \dots, n-1$$

and, of course,  $c_n = 0$ .

Having completed the elimination, we examine the new system and see that the  $n$ th equation is now

$$u_n = d'_n$$

Substituting this value into the  $(n-1)$ st equation,

$$u_{n-1} + c'_{n-1} u_n = d'_{n-1}$$

we have

$$u_{n-1} = d'_{n-1} - c'_{n-1} u_n$$

Thus, starting with  $u_n$ , we have successively the solution for  $u_i$  as

$$u_i = d'_i - c'_i u_{i+1}, \quad i = n-1, n-2, \dots, 1$$

### Algorithm for Pentadiagonal Matrix

The equations to be solved are

$$a_i u_{i-2} + b_i u_{i-1} + c_i u_i + d_i u_{i+1} + e_i u_{i+2} = f_i$$

for  $1 \leq i \leq R$  with  $a_1 = b_1 = a_2 = e_{R-1} = d_R = e_R = 0$ .

The algorithm is as follows. First, compute

$$\delta_1 = d_1/c_1$$

$$\lambda_1 = e_1/c_1$$

$$\gamma_1 = f_1/c_1$$

and

$$\begin{aligned}
\mu_2 &= c_2 - b_2 \delta_1 \\
\delta_2 &= (d_2 - b_2 \lambda_1) / \mu_2 \\
\lambda_2 &= e_2 / \mu_2 \\
\gamma_2 &= (f - b_2 \gamma_1) / \mu_2
\end{aligned}$$

Then, for  $3 \leq i \leq R - 2$  , compute

$$\begin{aligned}
\beta_i &= b_i - a_i \delta_{i-2} \\
\mu_i &= c_i - \beta_i \delta_{i-1} - a_i \lambda_{i-2} \\
\delta_i &= (d_i - \beta_i \lambda_{i-1}) / \mu_i \\
\lambda_i &= e_i / \mu_i \\
\gamma_i &= (f_i - \beta_i \gamma_{i-1} - a_i \gamma_{i-2}) / \mu_i
\end{aligned}$$

Next, compute

$$\begin{aligned}
\beta_{R-1} &= b_{R-1} - a_{R-1} \delta_{R-3} \\
\mu_{R-1} &= c_{R-1} - \beta_{R-1} \delta_{R-2} - a_{R-1} \lambda_{R-3} \\
\delta_{R-1} &= (d_{R-1} - \beta_{R-1} \lambda_{R-2}) / \mu_{R-1} \\
\gamma_{R-1} &= (f_{R-1} - \beta_{R-1} \gamma_{R-2} - a_{R-1} \gamma_{R-3}) / \mu_{R-1}
\end{aligned}$$

and

$$\begin{aligned}
\beta_R &= b_R - a_R \delta_{R-2} \\
\mu_R &= c_R - \beta_R \delta_{R-1} - a_R \lambda_{R-2} \\
\gamma_R &= (f_R - \beta_R \gamma_{R-1} - a_R \gamma_{R-2}) / \mu_R
\end{aligned}$$

The  $\beta_i$  and  $\mu_i$  are used only to compute  $\delta_i$ ,  $\lambda_i$ , and  $\gamma_i$ , and need not be stored after they are computed. The  $\delta_i$ ,  $\lambda_i$ , and  $\gamma_i$  must be stored, as they are used in the back solution. This is

$$\begin{aligned}
u_R &= \gamma_R \\
u_{R-1} &= \gamma_{R-1} - \delta_{R-1} u_R
\end{aligned}$$

and

$$u_i = \gamma_i - \delta_i u_{i+1} - \lambda_i u_{i+2}$$

for  $R - 2 \geq i \geq 1$  .

### General Band Algorithm

The equations are of the form

$$A_j^{(M)} X_{j-M} + A_j^{(M-1)} X_{j-M+1} + \cdots + A_j^{(2)} X_{j-2} + A_j^{(1)} X_{j-1} + B_j X_j \\ + C_j^{(1)} X_{j+1} + C_j^{(2)} X_{j+2} + \cdots + C_j^{(M-1)} X_{j+M-1} + C_j^{(M)} X_{j+M} = D_j$$

for  $1 \leq j \leq N$  ,  $N \geq M$  . The algorithm used is as follows:

$$\alpha_j^{(k)} = A_j^{(k)} = 0, \quad \text{for } k \geq j \\ C_j^{(k)} = 0, \quad \text{for } k \geq N + 1 - j$$

The forward solution ( $j = 1, \dots, N$ ) is

$$\alpha_j^{(k)} = A_j^{(k)} - \sum_{p=k+1}^{p=M} \alpha_j^{(p)} W_{j-p}^{(p-k)}, \quad k = M, \dots, 1 \\ \beta_j = B_j - \sum_{p=1}^M \alpha_j^{(p)} W_{j-p}^{(p)} \\ W_j^{(k)} = \left( C_j^{(k)} - \sum_{p=k+1}^{p=M} \alpha_j^{(p-k)} W_{j-(p-k)}^{(p)} \right) / \beta_j, \quad k = 1, \dots, M \\ \gamma_j = \left( D_j - \sum_{p=1}^M \alpha_j^{(p)} \gamma_{j-p} \right) / \beta_j$$

The back solution ( $j = N, \dots, 1$ ) is

$$X_j = \gamma_j - \sum_{p=1}^M W_j^{(p)} X_{j+p}$$

### Cholesky Decomposition

When the matrix  $A$  is a symmetric and positive definite, as it is for many discretizations of self-adjoint positive definite boundary value problems, one can improve considerably on the band procedures by using the Cholesky decomposition. For the system  $Au = v$ , the matrix  $A$  can be

written in the form

$$A = (I + L)D(I + U)$$

where  $L$  is lower triangular,  $U$  is upper triangular, and  $D$  is diagonal. If  $A = A'$  ( $A'$  represents the transpose of  $A$ ), then

$$A = A' = (I + U)'D(I + L)'$$

Hence, because of the uniqueness of the decomposition,

$$I + L = (I + U)' = I + U'$$

and therefore,

$$A = (I + U)'D(I + U)$$

that is,

$$A = B'B, \text{ where } B = \sqrt{D}(I + U)$$

The system  $Au = v$  is then solved by solving the two triangular system

$$B'w = v$$

followed by

$$Bu = w$$

To carry out the decomposition  $A = B'B$ , all elements of the first row of  $A$ , and of the derived system, are divided by the square root of the (positive) leading coefficient. This yields smaller rounding errors than the banded methods because the relative error of  $\sqrt{a}$  is only half as large as that of  $a$  itself. Also, taking the square root brings numbers nearer to each other (i.e., the new coefficients do not differ as widely as the original ones do). The actual computation of  $B = (b_{ij}), j > i$ , is given in the following:

$$\begin{aligned}
b_{11} &= (a_{11})^{1/2}, & b_{1j} &= a_{1j}/b_{11}, & j &\geq 2 \\
b_{22} &= (a_{22} - b_{12}^2)^{1/2}, & b_{2j} &= (a_{2j} - b_{12}b_{1j})/b_{22} \\
b_{33} &= (a_{33} - b_{13}^2 - b_{23}^2)^{1/2}, & b_{3j} &= (a_{3j} - b_{13}b_{1j} - b_{23}b_{2j})/b_{33} \\
&\vdots \\
b_{ii} &= \left( a_{ii} - \sum_{k=1}^{i-1} b_{ki}^2 \right)^{1/2}, & b_{ij} &= \left( a_{ij} - \sum_{k=1}^{i-1} b_{ki}b_{kj} \right) / b_{ii}, & i &\geq 2, j \geq 2
\end{aligned}$$

## Iterative Methods

Iterative methods consist of repeated application of an often simple algorithm. They yield the exact answer only as the limit of a sequence. They can be programmed to take care of zeros in  $A$  and are self-correcting. Their structure permits the use of convergence accelerators, such as overrelaxation, Aitkins acceleration, or Chebyshev acceleration.

Let  $a_{ii} > 0$  for all  $i$  and  $\det A \neq 0$ . With  $A = U + D + L$  as previously described, several iteration methods are described for  $(U + D + L)u = v$ .

### Jacobi Method (Iteration by total steps)

Since  $u = -D^{-1}[U + L]u + D^{-1}v$ , the iteration  $u^{(k)}$  is  $u^{(k)} = -D^{-1}[U + L]u^{(k-1)} + D^{-1}v$ . This procedure has a slow convergent rate designated by  $R$ ,  $0 < R \ll 1$ .

### Gauss-Seidel Method (Iteration by single steps)

$u^{(k)} = -(L + D)^{-1} U u^{(k-1)} + (L + D)^{-1} v$ . Convergence rate is  $2R$ , twice as fast as that of the Jacobi method.

### Gauss-Seidel with Successive Overrelaxation (SOR)

Let  $\bar{u}_i^{(k)}$  be the  $i$ th components of the Gauss-Seidel iteration. The SOR technique is defined by

$$u_i^{(k)} = (1 - \omega)u_i^{(k-1)} + \omega\bar{u}_i^{(k)}$$

where  $1 < \omega < 2$  is the overrelaxation parameter. The full iteration is

$u^{(k)} = (D + \omega L)^{-1} \{[(1 - \omega)D - \omega U]u^{(k-1)} + \omega v\}$ . Optimal values of  $\omega$  can be computed and depend upon the properties of  $A$  [Ames, 1993]. With optimal values of  $\omega$ , the convergence rate of this method is  $2R\sqrt{2}$  which is much larger than that for Gauss-Seidel ( $R$  is usually much less than one).

For other acceleration techniques, see the literature [Ames, 1993].

## 209.2 Nonlinear Equations in One Variable

---

### Special Methods for Polynomials

The polynomial  $P(x) = a_0x^n + a_1x^{n-1} + \cdots + a_{n-1}x + a_n = 0$ , with real coefficients  $a_j, j = 0, \dots, n$ , has exactly  $n$  roots which may be real or complex.

If all the coefficients of  $P(x)$  are integers, then any rational roots, say  $r/s$  ( $r$  and  $s$  are integers with no common factors), of  $P(x) = 0$  must be such that  $r$  is an integral divisor of  $a_n$  and  $s$  is an integral division of  $a_0$ . Any polynomial with rational coefficients may be converted into one with integral coefficients by multiplying the polynomial by the lowest common multiple of the denominators of the coefficients.

**Example.**  $x^4 - 5x^2/3 + x/5 + 3 = 0$ . The lowest common multiple of the denominators is 15. Multiplying by 15, which does not change the roots, gives  $15x^4 - 25x^2 + 3x + 45 = 0$ . The only possible rational roots  $r/s$  are such that  $r$  may have the value  $\pm 45, \pm 15, \pm 5, \pm 3$ , and  $\pm 1$ , while  $s$  may have the values  $\pm 15, \pm 5, \pm 3$ , and  $\pm 1$ . All possible rational roots, with no common factors, are formed using all possible quotients.

If  $a_0 > 0$ , the first negative coefficient is preceded by  $k$  coefficients which are positive or zero, and  $G$  is the largest of the absolute values of the negative coefficients, then each real root is less than  $1 + \sqrt[k]{G/a_0}$  (upper bound on the real roots). For a lower bound to the real roots, apply the criterion to  $P(-x) = 0$ .

**Example.**  $P(x) = x^5 + 3x^4 - 2x^3 - 12x + 2 = 0$ . Here  $a_0 = 1$ ,  $G = 12$ , and  $k = 2$ . Thus, the upper bound for the real roots is  $1 + \sqrt[2]{12} \approx 4.464$ . For the lower bound,  $P(-x) = -x^5 + 3x^4 + 2x^3 + 12x + 2 = 0$ , which is equivalent to  $x^5 - 3x^4 - 2x^3 - 12x - 2 = 0$ . Here  $k = 1$ ,  $G = 12$ , and  $a_0 = 1$ . A lower bound is  $-(1+12) = -13$ . Hence all real roots lie in  $-13 < x < 1 + \sqrt[2]{12}$ .

A useful *Descartes rule of signs* for the number of positive or negative real roots is available by observation for polynomials with real coefficients. The number of positive real roots is either equal to the number of sign changes,  $n$ , or is less than  $n$  by a positive *even* integer. The number of negative real roots is either equal to the number of sign changes,  $n$ , of  $P(-x)$ , or is less than  $n$  by a positive even integer.

**Example.**  $P(x) = x^5 - 3x^3 - 2x^2 + x - 1 = 0$ . There are three sign changes, so  $P(x)$  has either three or one positive roots. Since  $P(-x) = -x^5 + 3x^3 - 2x^2 - x - 1 = 0$ , there are either two or zero negative roots.

### The Graeffe Root-Squaring Technique

This is an iterative method for finding the roots of the algebraic equation

$$f(x) = a_0x^p + a_1x^{p-1} + \cdots + a_{p-1}x + a_p = 0$$

If the roots are  $r_1, r_2, r_3, \dots$ , then one can write

$$S_p = r_1^p \left( 1 + \frac{r_2^p}{r_1^p} + \frac{r_3^p}{r_1^p} + \cdots \right)$$

and if one root is larger than all the others, say  $r_1$ , then for large enough  $p$  all terms (other than 1) would become negligible. Thus,

$$S_p \approx r_1^p$$

or

$$\lim_{p \rightarrow \infty} S_p^{1/p} = r_1$$

The Graeffe procedure provides an efficient way for computing  $S_p$  via a sequence of equations such that the roots of each equation are the squares of the roots of the preceding equations in the sequence. This serves the purpose of ultimately obtaining an equation whose roots are so widely separated in magnitude that they may be read approximately from the equation by inspection. The basic procedure is illustrated for a polynomial of degree 4:

$$f(x) = a_0x^4 + a_1x^3 + a_2x^2 + a_3x + a_4 = 0$$

Rewrite this as

$$a_0x^4 + a_2x^2 + a_4 = -a_1x^3 - a_3x$$

and square both sides so that upon grouping

$$a_0^2x^8 + (2a_0a_2 - a_1^2)x^6 + (2a_0a_4 - 2a_1a_3 + a_2^2)x^4 + (2a_2a_4 - a_3^2)x^2 + a_4^2 = 0$$

Because this involves only even powers of  $x$ , we may set  $y = x^2$  and rewrite it as

$$a_0^2y^4 + (2a_0a_2 - a_1^2)y^3 + (2a_0a_4 - 2a_1a_3 + a_2^2)y^2 + (2a_2a_4 - a_3^2)y + a_4^2 = 0$$

whose roots are the squares of the original equation. If we repeat this process again, the new equation has roots which are the fourth power, and so on. After  $p$  such operations, the roots are  $2^p$  (original roots). If at any stage we write the coefficients of the unknown in sequence

$$a_0^{(p)} \quad a_1^{(p)} \quad a_2^{(p)} \quad a_3^{(p)} \quad a_4^{(p)}$$

then, to get the new sequence  $a^{(p+1)}$ , write  $a^{(p+1)}_i = 2a^{(p)}_0$  (times the symmetric coefficient) with respect to  $a^{(p)}_i - 2a^{(p)}_1$  (times the symmetric coefficient)  $-\cdots (-1)^i a^{(p)}_{i/2}$ . Now if the roots are  $r_1, r_2, r_3$ , and  $r_4$ , then  $a_1/a_0 = -\sum_{i=1}^4 r_i$ ,  $a_2/a_0 = -\sum_{i=1}^4 r_i^2, \dots, a_1^{(p)}/a_0^{(p)} = -\sum_{i=1}^4 r_i^{2^p}$ . If the roots

are all distinct and  $r_1$  is the largest in magnitude, then eventually

$$r_1^{2^p} \approx -\frac{a_1^{(p)}}{a_0^{(p)}}$$

And, if  $r_2$  is the next largest in magnitude, then

$$r_2^{2^p} \approx -\frac{a_2^{(p)}}{a_1^{(p)}}$$

And, in general,  $a_n^{(p)} / a_{n-1}^{(p)} \approx -r_n^{2^p}$ . This procedure is easily generalized to polynomials of arbitrary degree and specialized to the case of multiple and complex roots.

Other methods include Bernoulli iteration, Bairstow iteration, and Lin iteration. These may be found in the cited literature. In addition, the methods given below may be used for the numerical solution of polynomials.

## 209.3 General Methods for Nonlinear Equations in One Variable

---

### Successive Substitutions

Let  $f(x) = 0$  be the nonlinear equation to be solved. If this is rewritten as  $x = F(x)$ , then an iterative scheme can be set up in the form  $x_{k+1} = F(x_k)$ . To start the iteration, an initial guess must be obtained graphically or otherwise. The convergence or divergence of the procedure depends upon the method of writing  $x = F(x)$ , of which there will usually be several forms. A general rule to ensure convergence cannot be given. However, if  $a$  is a root of  $f(x) = 0$ , a necessary condition for convergence is that  $|F'(x)| < 1$  in that interval about  $a$  in which the iteration proceeds (this means the iteration cannot converge unless  $|F'(x)| < 1$ , but it does not ensure convergence). This process is called *first order* because the error in  $x_{k+1}$  is proportional to the first power of the error in  $x_k$ .

**Example.**  $f(x) = x^3 - x - 1 = 0$ . A rough plot shows a real root of approximately 1.3. The equation can be written in the form  $x = F(x)$  in several ways, such as  $x = x^3 - 1$ ,  $x = 1/(x^2 - 1)$ , and  $x = (1 + x)^{1/3}$ . In the first case,  $F'(x) = 3x^2 = 5.07$  at  $x = 1.3$ ; in the second,  $F(1.3) = 5.46$ ; only in the third case is  $F'(1.3) < 1$ . Hence, only the third iterative process has a chance to converge. This is illustrated in the iteration table below.

Step $k$	$x = \frac{1}{x^2 - 1}$	$x = x^3 - 1$	$x = (1 + x)^{1/3}$
0	1.3	1.3	1.3
1	1.4493	1.197	1.32

2	0.9087	0.7150	1.3238
3	-5.737	-0.6345	1.3247
4	...	...	1.3247

---

## 209.4 Numerical Solution of Simultaneous Nonlinear Equations

---

The techniques illustrated here will be demonstrated for two simultaneous equations— $f(x,y) = 0$  and  $g(x,y) = 0$ . They immediately generalize to more than two simultaneous equations.

### The Method of Successive Substitutions

The two simultaneous equations can be written in various ways in equivalent forms

$$x = F(x, y)$$

$$y = G(x, y)$$

and the method of successive substitutions can be based on

$$x_{k+1} = F(x_k, y_k)$$

$$y_{k+1} = G(x_k, y_k)$$

Again, the procedure is of the first order and a necessary condition for convergence is

$$\left| \frac{\partial F}{\partial x} \right| + \left| \frac{\partial F}{\partial y} \right| < 1 \quad \left| \frac{\partial G}{\partial x} \right| + \left| \frac{\partial G}{\partial y} \right| < 1$$

in the iteration neighborhood of the true solution.

### The Newton-Raphson Procedure

Using the two simultaneous equations, start from an approximation, say  $(x_0, y_0)$ , obtained graphically or from a two-way table. Then, solve successively the linear equations

$$\Delta x_k \frac{\partial f}{\partial x}(x_k, y_k) + \Delta y_k \frac{\partial f}{\partial y}(x_k, y_k) = -f(x_k, y_k)$$

$$\Delta x_k \frac{\partial g}{\partial x}(x_k, y_k) + \Delta y_k \frac{\partial g}{\partial y}(x_k, y_k) = -g(x_k, y_k)$$

for  $\Delta x_k$  and  $\Delta y_k$ . Then, the  $k + 1$  approximation is given from  $x_{k+1} = x_k + \Delta x_k$ ,  $y_{k+1} = y_k + \Delta y_k$ . A modification consists in solving the equations with  $(x_k, y_k)$  replaced by  $(x_0, y_0)$  (or another suitable pair later on in the iteration) in the derivatives. This means the derivatives (and therefore the coefficients of  $\Delta x_k, \Delta y_k$ ) are independent of  $k$ . Hence, the results become

$$\Delta x_k = \frac{-f(x_k, y_k)(\partial g/\partial y)(x_0, y_0) + g(x_k, y_k)(\partial f/\partial y)(x_0, y_0)}{(\partial f/\partial x)(x_0, y_0)(\partial g/\partial y)(x_0, y_0) - (\partial f/\partial y)(x_0, y_0)(\partial g/\partial x)(x_0, y_0)}$$

$$\Delta y_k = \frac{-g(x_k, y_k)(\partial f/\partial x)(x_0, y_0) + f(x_k, y_k)(\partial g/\partial x)(x_0, y_0)}{(\partial f/\partial x)(x_0, y_0)(\partial g/\partial y)(x_0, y_0) - (\partial f/\partial y)(x_0, y_0)(\partial g/\partial x)(x_0, y_0)}$$

and  $x_{k+1} = \Delta x_k + x_k$ ,  $y_{k+1} = \Delta y_k + y_k$ . Such an alteration of the basic technique reduces the rapidity of convergence.

### Example

$$f(x, y) = 4x^2 + 6x - 4xy + 2y^2 - 3$$

$$g(x, y) = 2x^2 - 4xy + y^2$$

By plotting, one of the approximate roots is found to be  $x_0 = 0.4$ ,  $y_0 = 0.3$ . At this point, there results  $\partial f/\partial x = 8$ ,  $\partial f/\partial y = -0.4$ ,  $\partial g/\partial x = 0.4$ , and  $\partial g/\partial y = -1$ . Hence,

$$x_{k+1} = x_k + \Delta x_k = x_k + \frac{-f(x_k, y_k) - 0.4g(x_k, y_k)}{8(-1) - (-0.4)(0.4)}$$

$$= x_k - 0.12755f(x_k, y_k) - 0.05102g(x_k, y_k)$$

and

$$y_{k+1} = y_k - 0.05102f(x_k, y_k) + 1.02041g(x_k, y_k)$$

The first few iteration steps are shown in the following table.

Step $k$	$x_k$	$y_k$	$f(x_k, y_k)$	$g(x_k, y_k)$
0	0.4	0.3	-0.26	0.07
1	0.43673	0.24184	0.078	0.0175
2	0.42672	0.25573	-0.0170	-0.007
3	0.42925	0.24943	0.0077	0.0010

## Methods of Perturbation

Let  $f(x) = 0$  be the equation. In general, the iterative relation is

$$x_{k+1} = x_k - \frac{f(x_k)}{\alpha_k}$$

where the iteration begins with  $x_0$  as an initial approximation and  $\alpha_k$  is some functional.

### The Newton-Raphson Procedure

This variant chooses  $\alpha_k = f'(x_k)$  where  $f' = df/dx$  and geometrically consists of replacing the graph of  $f(x)$  by the tangent line at  $x = x_k$  in each successive step. If  $f'(x)$  and  $f''(x)$  have the same sign throughout an interval  $a \leq x \leq b$  containing the solution, with  $f(a)$  and  $f(b)$  of opposite signs, then the process converges starting from any  $x_0$  in the interval  $a \leq x \leq b$ . The process is second order.

### Example

$$f(x) = x - 1 + \frac{(0.5)^x - 0.5}{0.3}$$

$$f'(x) = 1 - 2.3105[0.5]^x$$

An approximate root (obtained graphically) is 2.

Step $k$	$x_k$	$f(x_k)$	$f'(x_k)$
0	2	0.1667	0.4224
1	1.605	-0.002	0.2655
1	1.6125	-0.0005	...

### The Method of False Position

This variant is commenced by finding  $x_0$  and  $x_1$  such that  $f(x_0)$  and  $f(x_1)$  are of opposite signs. Then,  $\alpha_1 =$  slope of secant line joining  $[x_0, f(x_0)]$  and  $[x_1, f(x_1)]$  so that

$$x_2 = x_1 - \frac{x_1 - x_0}{f(x_1) - f(x_0)} f(x_1)$$

In each following step,  $\alpha_k$  is the slope of the line joining  $[x_k, f(x_k)]$  to the most recently determined point where  $f(x_j)$  has the opposite sign from that of  $f(x_k)$ . This method is of first order.

### The Method of Wegstein

This is a variant of the method of successive substitutions which forces or accelerates convergence.

The iterative procedure  $x_{k+1} = F(x_k)$  is revised by setting  $\hat{x}_{k+1} = F(x_k)$  and then taking  $x_{k+1} = qx_k + (1 - q)\hat{x}_{k+1}$ . Wegstein found that suitably chosen  $qs$  are related to the basic process as follows:

Behavior of Successive Substitution Process	Range of Optimum $q$
Oscillatory convergence	$0 < q < 1/2$
Oscillatory divergence	$1/2 < q < 1$
Monotonic convergence	$q < 0$
Monotonic divergence	$1 < q$

At each step,  $q$  may be calculated to give a locally optimum value by setting

$$q = \frac{x_{k+1} - x_k}{x_{k+1} - 2x_k + x_{k-1}}$$

## The Method of Continuity

In the case of  $n$  equations in  $n$  unknowns, when  $n$  is large, determining the approximate solution may involve considerable effort. In such a case, the method of continuity is admirably suited for use on either digital or analog computers. It consists basically of the introduction of an extra variable into the  $n$  equations

$$f_i(x_1, x_2, \dots, x_n) = 0, \quad i = 1, \dots, n$$

and replacing them by

$$f_i(x_1, x_2, \dots, x_n, \lambda) = 0, \quad i = 1, \dots, n$$

where  $\lambda$  is introduced in such a way that the functions depend in a simple way upon  $\lambda$  and reduce to an easily solvable system for  $\lambda = 0$  and to the original equations for  $\lambda = 1$ . A system of ordinary differential equations, with independent variable  $\lambda$ , is then constructed by differentiating with respect to  $\lambda$ . There results

$$\sum_{j=1}^n \frac{\partial f_i}{\partial x_j} \frac{dx_j}{d\lambda} + \frac{\partial f_i}{\partial \lambda} = 0$$

where  $x_1, \dots, x_n$  are considered as functions of  $\lambda$ . The equations are integrated, with initial conditions obtained with  $\lambda = 0$ , from  $\lambda = 0$  to  $\lambda = 1$ . If the solution can be continued to  $\lambda = 1$ , the values of  $x_1, \dots, x_n$  for  $\lambda = 1$  will be a solution of the original equations. If the integration becomes infinite, the parameter  $\lambda$  must be introduced in a different fashion. Integration of the differential equations (which are usually nonlinear in  $\lambda$ ) may be accomplished on an analog computer or by digital means using techniques described in a later section entitled "Numerical

## Solution of Ordinary Differential Equations."

### Example

$$f(x, y) = 2 + x + y - x^2 + 8xy + y^3 = 0$$

$$g(x, y) = 1 + 2x + 3y + x^2 + xy - ye^x = 0$$

Introduce  $\lambda$  as

$$f(x, y, \lambda) = (2 + x + y) + \lambda(-x^2 + 8xy + y^3) = 0$$

$$g(x, y, \lambda) = (1 + 2x - 3y) + \lambda(x^2 + xy - ye^x) = 0$$

For  $\lambda = 1$ , these reduce to the original equations, but, for  $\lambda = 0$ , they are the linear systems

$$x + y = -2$$

$$2x - 3y = -1$$

which has the unique solution  $x = -1.4$ ,  $y = -0.6$ . The differential equations in this case become

$$\frac{\partial f}{\partial x} \frac{dx}{d\lambda} + \frac{\partial f}{\partial y} \frac{dy}{d\lambda} = -\frac{\partial f}{\partial \lambda}$$

$$\frac{\partial g}{\partial x} \frac{dx}{d\lambda} + \frac{\partial g}{\partial y} \frac{dy}{d\lambda} = -\frac{\partial g}{\partial \lambda}$$

or

$$\frac{dx}{d\lambda} = \frac{\frac{\partial f}{\partial y} \frac{\partial g}{\partial \lambda} - \frac{\partial f}{\partial \lambda} \frac{\partial g}{\partial y}}{\frac{\partial f}{\partial x} \frac{\partial g}{\partial y} - \frac{\partial f}{\partial y} \frac{\partial g}{\partial x}}$$

$$\frac{dy}{d\lambda} = \frac{\frac{\partial f}{\partial \lambda} \frac{\partial g}{\partial x} - \frac{\partial f}{\partial x} \frac{\partial g}{\partial \lambda}}{\frac{\partial f}{\partial x} \frac{\partial g}{\partial y} - \frac{\partial f}{\partial y} \frac{\partial g}{\partial x}}$$

Integrating in  $\lambda$ , with initial values  $x = -1.4$  and  $y = -0.6$  at  $\lambda = 0$ , from  $\lambda = 0$  to  $\lambda = 1$  gives the solution.

## 209.5 Interpolation and Finite Differences

---

The practicing engineer constantly finds it necessary to refer to tables as sources of information. Consequently, interpolation, or that procedure of "reading between the lines of the table," is a necessary topic in numerical analysis.

### Linear Interpolation

If a function  $f(x)$  is approximately linear in a certain range, then the ratio  $[f(x_1) - f(x_0)]/(x_1 - x_0) = f[x_0, x_1]$  is approximately independent of  $x_0$  and  $x_1$  in the range. The linear approximation to the function  $f(x)$ ,  $x_0 < x < x_1$ , then leads to the interpolation formula

$$\begin{aligned} f(x) &\approx f(x_0) + (x - x_0)f[x_0, x_1] \approx f(x_0) + \frac{x - x_0}{x_1 - x_0}[f(x_1) - f(x_0)] \\ &\approx \frac{1}{x_1 - x_0}[(x_1 - x)f(x_0) - (x_0 - x)f(x_1)] \end{aligned}$$

### Divided Differences of Higher Order and Higher-Order Interpolation

The first-order divided difference  $f[x_0, x_1]$  was defined above. Divided differences of second and higher order are defined iteratively by

$$\begin{aligned} f[x_0, x_1, x_2] &= \frac{f[x_1, x_2] - f[x_0, x_1]}{x_2 - x_0} \\ &\vdots \\ f[x_0, x_1, \dots, x_k] &= \frac{f[x_1, \dots, x_k] - f[x_0, x_1, \dots, x_{k-1}]}{x_k - x_0} \end{aligned}$$

and a convenient form for computational purposes is

$$f[x_0, x_1, \dots, x_k] = \sum_{j=0}^k ' \frac{f(x_j)}{(x_j - x_0)(x_j - x_1) \cdots (x_j - x_k)}$$

for any  $k \geq 0$ , where the ' means the term  $(x_j - x_j)$  is omitted in the denominator. For example,

$$f[x_0, x_1, x_2] = \frac{f(x_0)}{(x_0 - x_1)(x_0 - x_2)} + \frac{f(x_1)}{(x_1 - x_0)(x_1 - x_2)} + \frac{f(x_2)}{(x_2 - x_0)(x_2 - x_1)}$$

If the accuracy afforded by a linear approximation is inadequate, a generally more accurate result may be based upon the assumption that  $f(x)$  may be approximated by a polynomial of degree 2 or higher over certain ranges. This assumption leads to *Newton's fundamental interpolation formula* with divided differences:

$$f(x) \approx f(x_0) + (x - x_0)f[x_0, x_1] + (x - x_0)(x - x_1)f[x_0, x_1, x_2] \\ + (x - x_0)(x - x_1) \cdots (x - x_{n-1})f[x_0, x_1, \dots, x_n] + E_n(x)$$

where  $E_n(x)$  = error =  $[1/(n+1)] f^{(n+1)}(\xi) \pi(x)$  where

$\min(x_0, \dots, x_n) < \xi < \max(x_0, x_1, \dots, x_n, x)$  and  $\pi(x) = (x - x_0)(x - x_1) \cdots (x - x_n)$ . In order to use this most effectively, one may first form a divided-difference table. For example, for third-order interpolation, the difference table is

$x_0$	$f(x_0)$			
		$f[x_0, x_1]$		
$x_1$	$f(x_1)$		$f[x_0, x_1, x_2]$	
		$f[x_1, x_2]$		$f[x_0, x_1, x_2, x_3]$
$x_2$	$f(x_2)$		$f[x_1, x_2, x_3]$	
		$f[x_2, x_3]$		
$x_3$	$f(x_3)$			

where each entry is given by taking the difference between diagonally adjacent entries to the left, divided by the abscissas corresponding to the ordinates intercepted by the diagonals passing through the calculated entry.

**Example.** Calculate by third-order interpolation the value of  $\cosh 0.83$  given  $\cosh 0.60$ ,  $\cosh 0.80$ ,  $\cosh 0.90$ , and  $\cosh 1.10$ .

$x_0 = 0.60$	1.185 47			
		0.7598		
$x_1 = 0.80$	1.337 43		0.6560	
		0.9566		0.1586
$x_2 = 0.90$	1.433 09		0.7353	
		1.1772		
$x_3 = 1.10$	1.668 52			

With  $n = 3$ , we have

$$\cosh 0.83 \approx 1.185 47 + (0.23)(0.7598) + (0.23)(0.03)(0.6560) \\ + (0.23)(0.03)(-0.07)(0.1586) = 1.364 64$$

which varies from the true value by 0.000 04.

## Lagrange Interpolation Formulas

The Newton formulas are expressed in terms of divided differences. It is often useful to have interpolation formulas expressed explicitly in terms of the ordinates involved. This is accomplished by the Lagrange interpolation polynomial of degree  $n$ :

$$y(x) = \sum_{j=0}^n \frac{\pi(x)}{(x - x_j)\pi'(x_j)} f(x_j)$$

where

$$\begin{aligned}\pi(x) &= (x - x_0)(x - x_1) \cdots (x - x_n) \\ \pi'(x_j) &= (x_j - x_0)(x_j - x_1) \cdots (x_j - x_n)\end{aligned}$$

where  $(x_j - x_j)$  is the omitted factor. Thus,

$$f(x) = y(x) + E_n(x)$$

$$E_n(x) = \frac{1}{(n+1)!} \pi(x) f^{(n+1)}(\varepsilon)$$

**Example.** The interpolation polynomial of degree 3 is

$$\begin{aligned}y(x) &= \frac{(x - x_1)(x - x_2)(x - x_3)}{(x_0 - x_1)(x_0 - x_2)(x_0 - x_3)} f(x_0) + \frac{(x - x_0)(x - x_2)(x - x_3)}{(x_1 - x_0)(x_1 - x_2)(x_1 - x_3)} f(x_1) \\ &+ \frac{(x - x_0)(x - x_1)(x - x_3)}{(x_2 - x_0)(x_2 - x_1)(x_2 - x_3)} f(x_2) + \frac{(x - x_0)(x - x_1)(x - x_2)}{(x_3 - x_0)(x_3 - x_1)(x_3 - x_2)} f(x_3)\end{aligned}$$

Thus, directly from the data

$x$	0	1	3	4
$f(x)$	1	1	-1	2

we have as an interpolation polynomial  $y(x)$  for  $f(x)$ :

$$\begin{aligned}y(x) &= 1 \cdot \frac{(x - 1)(x - 3)(x - 4)}{(0 - 1)(0 - 3)(0 - 4)} + 1 \cdot \frac{x(x - 3)(x - 4)}{(1 - 0)(1 - 3)(1 - 4)} \\ &- 1 \cdot \frac{x(x - 1)(x - 4)}{(3 - 0)(3 - 1)(3 - 4)} + 2 \cdot \frac{(x - 0)(x - 1)(x - 3)}{(4 - 0)(4 - 1)(4 - 3)}\end{aligned}$$

## Other Difference Methods (Equally Spaced Ordinates)

### Backward Differences

The backward differences denoted by

$$\begin{aligned}\nabla f(x) &= f(x) - f(x - h) \\ \nabla^2 f(x) &= \nabla f(x) - \nabla f(x - h) \\ &\dots \\ \nabla^n f(x) &= \nabla^{n-1} f(x) - \nabla^{n-1} f(x - h)\end{aligned}$$

are useful for calculation near the end of tabulated data.

### Central Differences

The central difference denoted by

$$\begin{aligned}\delta f(x) &= f\left(x + \frac{h}{2}\right) - f\left(x - \frac{h}{2}\right) \\ \delta^n f(x) &= \delta^{n-1} f\left(x + \frac{h}{2}\right) - \delta^{n-1} f\left(x - \frac{h}{2}\right)\end{aligned}$$

is useful for calculating at the interior points of tabulated data.

Also to be found in the literature are Gaussian, Stirling, Bessel, Everett, Comrie differences, and so forth.

## Inverse Interpolation

This is the process of finding the value of the independent variable or abscissa corresponding to a given value of the function when the latter is between two tabulated values of the abscissa. One method of accomplishing this is to use Lagrange's interpolation formula in the form

$$x = \psi(y) = \sum_{j=0}^n \frac{\pi(y)}{(y - y_j)\pi'(y_j)} x_j$$

where  $x$  is expressed as a function of  $y$ . Other methods revolve about methods of iteration.

## 209.6 Numerical Differentiation

---

Numerical differentiation should be avoided wherever possible, particularly when data are empirical and subject to appreciable observation errors. Errors in data can affect numerical derivatives quite strongly (i.e., differentiation is a roughening process). When such a calculation

must be made, it is usually desirable first to *smooth* the data to a certain extent.

## The Use of Interpolation Formulas

If the data are given over equidistant values of the independent variable  $x$ , an interpolation formula, such as the Newton formula, may be used, and the resulting formula differentiated analytically. If the independent variable is not at equidistant values, then Lagrange's formulas must be used. By differentiating three- and five-point Lagrange interpolation formulas, the following differentiation formulas result for equally spaced tabular points.

### Three-point Formulas

Let  $x_0$ ,  $x_1$ , and  $x_2$  be the three points.

$$f'(x_0) = \frac{1}{2h} [-3f(x_0) + 4f(x_1) - f(x_2)] + \frac{h^2}{3} f'''(\varepsilon)$$

$$f'(x_1) = \frac{1}{2h} [-f(x_0) + f(x_2)] + \frac{h^2}{6} f'''(\varepsilon)$$

$$f'(x_2) = \frac{1}{2h} [f(x_0) - 4f(x_1) + 3f(x_2)] + \frac{h^2}{3} f'''(\varepsilon)$$

where the last term is an error term and  $\min_j x_j < \varepsilon < \max_j x_j$ .

### Five-point Formulas

Let  $x_0$ ,  $x_1$ ,  $x_2$ ,  $x_3$ , and  $x_4$  be the five values of the equally spaced independent variable and  $f_j = f(x_j)$ .

$$f'(x_0) = \frac{1}{12h} [-25f_0 + 48f_1 - 36f_2 + 16f_3 - 3f_4] + \frac{h^4}{5} f^{(v)}(\varepsilon)$$

$$f'(x_1) = \frac{1}{12h} [-3f_0 - 10f_1 + 18f_2 - 6f_3 + f_4] - \frac{h^4}{20} f^{(v)}(\varepsilon)$$

$$f'(x_2) = \frac{1}{12h} [f_0 - 8f_1 + 8f_3 - f_4] + \frac{h^4}{30} f^{(v)}(\varepsilon)$$

$$f'(x_3) = \frac{1}{12h} [-f_0 + 6f_1 - 18f_2 + 10f_3 + 3f_4] - \frac{h^4}{20} f^{(v)}(\varepsilon)$$

$$f'(x_4) = \frac{1}{12h} [3f_0 - 16f_1 + 36f_2 - 48f_3 + 25f_4] + \frac{h^4}{5} f^{(v)}(\varepsilon)$$

and the last term is again an error term.

## Smoothing Techniques

These techniques involve the approximation of the tabular data by a least squares fit of the data

using some known functional form, usually a polynomial. In place of approximating  $f(x)$  by a single least squares polynomial of degree  $n$  over the entire range of the tabulation, it is often desirable to replace each tabulated value by the value taken on by a least squares polynomial of degree  $n$  relevant to a subrange of  $2M + 1$  points centered, where possible, at the point for which the entry is to be modified. Thus, each smoothed value replaces a tabulated value. Let  $f_j = f(x_j)$  be the tabular points and  $y_j$  = smoothed values. A first-degree least squares with three points would be

$$\begin{aligned}y_0 &= \frac{1}{6}[5f_0 + 2f_1 - f_2] \\y_1 &= \frac{1}{3}[f_0 + f_1 + f_2] \\y_2 &= \frac{1}{6}[-f_0 + 2f_1 + 5f_2]\end{aligned}$$

A first-degree least squares with five points would be

$$\begin{aligned}y_0 &= \frac{1}{5}[3f_0 + 2f_1 + f_2 - f_4] \\y_1 &= \frac{1}{10}[4f_0 + 3f_1 + 2f_2 + f_3] \\y_2 &= \frac{1}{5}[f_0 + f_1 + f_2 + f_3 + f_4] \\y_3 &= \frac{1}{10}[f_0 + 2f_1 + 3f_2 + 4f_3] \\y_4 &= \frac{1}{5}[-f_0 + f_2 + 2f_3 + 3f_4]\end{aligned}$$

Thus, for example, if first-degree, five-point least squares are used, the central formula is used for all values except the first two and the last two, where the off-center formulas are used. A third-degree least squares with seven points would be

$$\begin{aligned}y_0 &= \frac{1}{42}[39f_0 + 8f_1 - 4f_2 - 4f_3 + f_4 + 4f_5 - 2f_6] \\y_1 &= \frac{1}{42}[8f_0 + 19f_1 + 16f_2 + 6f_3 - 4f_4 - 7f_5 + 4f_6] \\y_2 &= \frac{1}{42}[-4f_0 + 16f_1 + 19f_2 + 12f_3 + 2f_4 - 4f_5 + f_6] \\y_3 &= \frac{1}{21}[-2f_0 + 3f_1 + 6f_2 + 7f_3 + 6f_4 + 3f_5 - 2f_6] \\y_4 &= \frac{1}{42}[f_0 - 4f_1 + 2f_2 + 12f_3 + 19f_4 + 16f_5 - 4f_6] \\y_5 &= \frac{1}{42}[4f_0 - 7f_1 - 4f_2 + 6f_3 + 16f_4 + 19f_5 + 8f_6] \\y_6 &= \frac{1}{42}[-2f_0 + 4f_1 + f_2 - 4f_3 - 4f_4 + 8f_5 + 39f_6]\end{aligned}$$

Additional smoothing formulas may be found in the references. After the data are smoothed, any of the interpolation polynomials, or an appropriate least squares polynomial, may be fitted and the results used to obtain the derivative.

## Least Squares Methods

### Parabolic

For five evenly spaced neighboring abscissas labeled  $x_{-2}$ ,  $x_{-1}$ ,  $x_0$ ,  $x_1$ , and  $x_2$ , and their ordinates  $f_{-2}$ ,  $f_{-1}$ ,  $f_0$ ,  $f_1$ , and  $f_2$ , assume a parabola is fit by least squares. There results for all interior points, except the first and last two points of the data, the formula for the numerical derivative:

$$f'_0 = \frac{1}{10h} [-2f_{-2} - f_{-1} + f_1 + 2f_2]$$

For the first two data points designated by 0 and  $h$ :

$$f'(0) = \frac{1}{20h} [-21f(0) + 13f(h) + 17f(2h) - 9f(3h)]$$

$$f'(h) = \frac{1}{20h} [-11f(0) + 3f(h) + 7f(2h) + f(3h)]$$

and for the last two given by  $\alpha - h$  and  $\alpha$ :

$$f'(\alpha - h) = \frac{1}{20h} [-11f(\alpha) + 3f(\alpha - h) + 7f(\alpha - 2h) + f(\alpha - 3h)]$$

$$f'(\alpha) = \frac{1}{20h} [-21f(\alpha) + 13f(\alpha - h) + 17f(\alpha - 2h) - 9f(\alpha - 3h)]$$

### Quartic (Douglas-Avakian)

A fourth-degree polynomial  $y = a + bx + cx^2 + dx^3 + ex^4$  is fitted to seven adjacent equidistant points (spacing  $h$ ) after a translation of coordinates has been made so that  $x = 0$  corresponds to the central point of the seven. Thus, these may be called  $-3h$ ,  $-2h$ ,  $-h$ ,  $0$ ,  $h$ ,  $2h$ , and  $3h$ . Let  $k =$  coefficient of  $h$  for the seven points. That is, in  $-3h$ ,  $k = -3$ . Then, the coefficients for the polynomial are

$$\begin{aligned}
a &= \frac{524 \sum f(kh) - 245 \sum k^2 f(kh) + 21 \sum k^4 f(kh)}{924} \\
b &= \frac{397 \sum k f(kh)}{1512h} - \frac{7 \sum k^3 f(kh)}{216h} \\
c &= \frac{-840 \sum f(kh) + 679 \sum k^2 f(kh) - 67 \sum k^4 f(kh)}{3168h^2} \\
d &= \frac{-7 \sum k f(kh) + \sum k^3 f(kh)}{216h^3} \\
e &= \frac{72 \sum f(kh) - 67 \sum k^2 f(kh) + 7 \sum k^4 f(kh)}{3168h^4}
\end{aligned}$$

where all summations run from  $k = -3$  to  $k = +3$  and  $f(kh)$  = tabular value at  $kh$ . The slope of the polynomial at  $x = 0$  is  $dy/dx = b$ .

## 209.7 Numerical Integration

---

Numerical evaluation of the finite integral  $\int_a^b f(x) dx$  is carried out by a variety of methods. A few are given here.

### Newton-Cotes Formulas (Equally Spaced Ordinates)

#### Trapezoidal Rule

This formula consists of subdividing the interval  $a \leq x \leq b$  into  $n$  subintervals  $a$  to  $a + h$ ,  $a + h$  to  $a + 2h$ , ..., and replacing the graph of  $f(x)$  by the result of joining the ends of adjacent ordinates by line segments. If  $f_j = f(x_j) = f(a + jh)$ ,  $f_0 = f(a)$ , and  $f_n = f(b)$ , the integration formula is

$$\int_a^b f(x) dx = \frac{h}{2} [f_0 + 2f_1 + 2f_2 + \cdots + 2f_{n-1} + f_n] + E_n$$

where  $|E_n| = (nh^3/12)|f''(\varepsilon)| = [(b-a)^3/12n^2]|f''(\varepsilon)|$ ,  $a < \varepsilon < b$ . This procedure is not of high accuracy. However, if  $f''(x)$  is continuous in  $a < x < b$ , the error goes to zero as  $1/n^2$ ,  $n \rightarrow \infty$ .

#### Parabolic Rule (Simpson's Rule)

This procedure consists of subdividing the interval  $a < x < b$  into  $n/2$  subintervals, each of length  $2h$ , where  $n$  is an even integer. Using the notation as above the integration formula is

$$\begin{aligned}
\int_a^b f(x) dx &= \frac{h}{3} [f_0 + 4f_1 + 2f_2 + 4f_3 + \cdots + 4f_{n-3} \\
&\quad + 2f_{n-2} + 4f_{n-1} + f_n] + E_n
\end{aligned}$$

where

$$|E_n| = \frac{nh^5}{180} |f^{(iv)}(\varepsilon)| = \frac{(b-a)^3}{180n^4} |f^{(iv)}(\varepsilon)| \quad a < \varepsilon < b$$

This method approximates  $f(x)$  by a parabola on each subinterval. This rule is generally more accurate than the trapezoidal rule. It is the most widely used integration formula.

### Weddle's Rule

This procedure consists of subdividing the integral  $a < x < b$  into  $n/6$  subintervals, each of length  $6h$ , where  $n$  is a multiple of 6. Using the notation from the trapezoidal rule, there results

$$\begin{aligned} \int_a^b f(x)dx &= \frac{3h}{10} [f_0 + 5f_1 + f_2 + 6f_3 + f_4 + 5f_5 + 2f_6 + 5f_7 + f_8 + \cdots \\ &\quad + 6f_{n-3} + f_{n-2} + 5f_{n-1} + f_n] + E_n \end{aligned}$$

Note that the coefficients of  $f_j$  follow the rule 1, 5, 1, 6, 1, 5, 2, 5, 1, 6, 1, 5, 2, 5, etc. . . This procedure consists of approximating  $f(x)$  by a polynomial of degree 6 on each subinterval. Here,

$$E_n = \frac{nh^7}{1400} [10f^{(6)}(\varepsilon_1) + 9h^2f^{(8)}(\varepsilon_2)]$$

## Gaussian Integration Formulas (Unequally Spaced Abscissas)

These formulas are capable of yielding comparable accuracy with fewer ordinates than the equally spaced formulas. The ordinates are obtained by optimizing the distribution of the abscissas rather than by arbitrary choice. For the details of these formulas, Hildebrand [1956] is an excellent reference.

## Two-Dimensional Formula

Formulas for two-way integration over a rectangle, circle, ellipse, and so forth, may be developed by a double application of one-dimensional integration formulas. The two-dimensional generalization of the parabolic rule is given here. Consider the iterated integral  $\int_a^b \int_c^d f(x, y) dx dy$ . Subdivide  $c < x < d$  into  $m$  (even) subintervals of length  $h = (d - c)/m$ , and  $a < y < b$  into  $n$  (even) subintervals of length  $k = (b - a)/n$ . This gives a subdivision of the rectangle  $a \leq y \leq b$  and  $c \leq x \leq d$  into subrectangles. Let  $x_j = c + jh$ ,  $y_j = a + jk$ , and  $f_{i,j} = f(x_i, y_j)$ . Then,

$$\begin{aligned} \int_a^b \int_c^d f(x, y) dx dy &= \frac{hk}{9} [(f_{0,0} + 4f_{1,0} + 2f_{2,0} + \cdots + f_{m,0}) \\ &\quad + 4(f_{0,1} + 4f_{1,1} + 2f_{2,1} + \cdots + f_{m,1}) \\ &\quad + 2(f_{0,2} + 4f_{1,2} + 2f_{2,2} + \cdots + f_{m,2}) + \cdots \\ &\quad + (f_{0,n} + 4f_{1,n} + 2f_{2,n} + \cdots + f_{m,n})] + E_{m,n} \end{aligned}$$

where

$$E_{m,n} = -\frac{hk}{90} \left[ mh^4 \frac{\partial^4 f(\varepsilon_1, \eta_1)}{\partial x^4} + nk^4 \frac{\partial^4 f(\varepsilon_2, \eta_2)}{\partial y^4} \right]$$

where  $\varepsilon_1$  and  $\varepsilon_2$  lie in  $c < x < d$ , and  $\eta_1$  and  $\eta_2$  lie in  $a < y < b$ .

## 209.8 Numerical Solution of Ordinary Differential Equations

---

A number of methods have been devised to solve ordinary differential equations numerically. The general references contain some information. A numerical solution of a differential equation means a table of values of the function  $y$  and its derivatives over only a limited part of the range of the independent variable. Every differential equation of order  $n$  can be rewritten as  $n$  first-order differential equations. Therefore, the methods given below will be for first-order equations, and the generalization to simultaneous systems will be developed later.

### The Modified Euler Method

This method is simple and yields modest accuracy. If extreme accuracy is desired, a more sophisticated method should be selected. Let the first-order differential equation be  $dy/dx = f(x, y)$  with the initial condition  $(x_0, y_0)$  (i.e.,  $y = y_0$  when  $x = x_0$ ). The procedure is as follows.

- Step 1. From the given initial conditions  $(x_0, y_0)$ , compute  $y'_0 = f(x_0, y_0)$  and  $y''_0 = [\partial f(x_0, y_0)/\partial x] + [\partial f(x_0, y_0)/\partial y]y'_0$ . Then, determine  $y_1 = y_0 + hy'_0 + (h^2/2)y''_0$ , where  $h$  = subdivision of the independent variable.
- Step 2. Determine  $y'_1 = f(x_1, y_1)$ , where  $x_1 = x_0 + h$ . These prepare us for the following.

#### Predictor Steps

- Step 3. For  $n \geq 1$ , calculate  $(y_{n+1})_1 = y_{n-1} + 2hy'_n$ .
- Step 4. Calculate  $(y'_{n+1})_1 = f[x_{n+1}, (y_{n+1})_1]$ .

#### Corrector Steps

- Step 5. Calculate  $(y_{n+1})_2 = y_n + (h/2)[(y'_{n+1})_1 + y'_n]$ , where  $y_n$  and  $y'_n$  without the

subscripts are the previous values obtained by this process (or by steps 1 and 2).

Step 6.  $(y'_{n+1})_2 = f[x_{n+1}, (y_{n+1})_2]$  .

Step 7. Repeat the corrector steps 5 and 6 if necessary until the desired accuracy is produced in  $y_{n+1}, y'_{n+1}$ .

**Example.** Consider the equation  $y' = 2y^2 + x$  with the initial conditions  $y_0 = 1$  when  $x_0 = 0$ . Let  $h = 0.1$ . A few steps of the computation are illustrated.

Step	
1	$y'_0 = 2y_0^2 + x_0 = 2$ $y''_0 = 1 + 4y_0y'_0 = 1 + 8 = 9$ $y_1 = 1 + (0.1)(2) + [(0.1)^2/2]9 = 1.245$
2	$y'_1 = 2y_1^2 + x_1 = 3.100 + 0.1 = 3.200$
3	$(y_2)_1 = y_0 + 2hy'_1 = 1 + 2(0.1)3.200 = 1.640$
4	$(y'_2)_1 = 2(y_2)_1^2 + x_2 + 5.592$
5	$(y_2)_2 = y_1 + (0.1/2)[(y'_2)_1 + y'_1] = 1.685$
6	$(y'_2)_2 = 2(y_2)_2^2 + x_2 = 5.878$
5 (repeat)	$(y_2)_3 = y_1 + (0.05)[(y'_2)_2 + y'_1] = 1.699$
6 (repeat)	$(y'_2)_3 = 2(y_2)_3^2 + x_2 = 5.974$

and so forth. This procedure may be programmed for a computer. A discussion of the truncation error of this process may be found in Milne [1953].

## Modified Adam's Method

The procedure given here was developed retaining third differences. It can then be considered as a more exact predictor-corrector method than the Euler method. The procedure is as follows for  $dy/dx = f(x,y)$  and  $h$  = interval size.

Steps 1 and 2 are the same as in the Euler method.

### Predictor Steps

Step 3.  $(y_{n+1})_1 = y_n + (h/24)[55y'_n - 59y'_{n-1} + 37y'_{n-2} - 9y'_{n-3}]$  , where  $y'_n, y'_{n-1}$  , etc, are calculated in step 1.

Step 4.  $(y'_{n+1})_1 = f[x_{n+1}, (y_{n+1})_1]$  .

### Corrector Steps

Step 5.  $(y_{n+1})_2 = y_n + (h/24)[9(y'_{n+1})_1 + 19y'_n - 5y'_{n-1} + y'_{n-2}]$  .

Step 6.  $(y'_{n+1})_2 = f[x_{n+1}, (y_{n+1})_2]$  .

Step 7. Iterate steps 5 and 6 if necessary.

## Runge-Kutta Methods

These methods are self-starting and are inherently stable. Kopal [1955] is a good reference for their derivation and discussion. Third- and fourth-order procedures are given below for  $dy/dx = f(x,y)$ , where  $h$  = interval size.

For third-order (error  $\approx h^4$ ),

$$\begin{aligned}k_0 &= hf(x_n, y_n) \\k_1 &= hf(x_n + \frac{1}{2}h, y_n + \frac{1}{2}k_0) \\k_2 &= hf(x_n + h, y_n + 2k_1 - k_0)\end{aligned}$$

and

$$y_{n+1} = y_n + \frac{1}{6}(k_0 + 4k_1 + k_2)$$

for all  $n \geq 0$ , with initial condition  $(x_0, y_0)$ .

For fourth-order (error  $\approx h^5$ ),

$$\begin{aligned}k_0 &= hf(x_n, y_n) \\k_1 &= hf(x_n + \frac{1}{2}h, y_n + \frac{1}{2}k_0) \\k_2 &= hf(x_n + \frac{1}{2}h, y_n + \frac{1}{2}k_1) \\k_3 &= hf(x_n + h, y_n + k_2)\end{aligned}$$

and

$$y_{n+1} = y_n + \frac{1}{6}(k_0 + 2k_1 + 2k_2 + k_3)$$

**Example.** (Third-order) Let  $dy/dx = x - 2y$ , with initial condition  $y_0 = 1$  when  $x_0 = 0$ , and let  $h = 0.1$ . Clearly,  $x_n = nh$ . To calculate  $y_1$ , proceed as follows:

$$\begin{aligned}k_0 &= 0.1[x_0 - 2y_0] = -0.2 \\k_1 &= 0.1[0.05 - 2(1 - 0.1)] = -0.175 \\k_2 &= 0.1[0.1 - 2(1 - 0.35 + 0.2)] = -0.16 \\y_1 &= 1 + \frac{1}{6}(-0.2 - 0.7 - 0.16) = 0.8234\end{aligned}$$

## Equations of Higher Order and Simultaneous Differential Equations

Any differential equation of second- or higher order can be reduced to a simultaneous system of first-order equations by the introduction of auxiliary variables. Consider the following equations:

$$\frac{d^2 x}{dt^2} + xy \frac{dx}{dt} + z = e^x$$

$$\frac{d^2 y}{dt^2} + xy \frac{dy}{dt} = 7 + t^2$$

$$\frac{d^2 z}{dt^2} + xz \frac{dz}{dt} + x = e^x$$

In the new variables  $x_1 = x$ ,  $x_2 = y$ ,  $x_3 = z$ ,  $x_4 = dx_1/dt$ ,  $x_5 = dx_2/dt$ , and  $x_6 = dx_3/dt$ , the equations become

$$\frac{dx_1}{dt} = x_4$$

$$\frac{dx_2}{dt} = x_5$$

$$\frac{dx_3}{dt} = x_6$$

$$\frac{dx_4}{dt} = -x_1 x_2 x_4 - x_3 + e^{x_1}$$

$$\frac{dx_5}{dt} = -x_3 x_2 x_5 + 7 + t^2$$

$$\frac{dx_6}{dt} = -x_1 x_3 x_6 - x_1 + e^{x_1}$$

which is a system of the general form

$$\frac{dx_i}{dt} = f_i(t, x_1, x_2, x_3, \dots, x_n)$$

where  $i = 1, 2, \dots, n$ . Such systems may be solved by simultaneous application of any of the above numerical techniques. A Runge-Kutta method for

$$\frac{dx}{dt} = f(t, x, y)$$

$$\frac{dy}{dt} = g(t, x, y)$$

is given below. The fourth-order procedure is shown.

Starting at the initial conditions  $x_0$ ,  $y_0$ , and  $t_0$ , the next values  $x_1$  and  $y_1$  are computed via the equations below (where  $\Delta t = h$ ,  $t_j = h + t_{j-1}$ ):

$$\begin{aligned} k_0 &= hf(t_0, x_0, y_0) & l_0 &= hg(t_0, x_0, y_0) \\ k_1 &= hf\left(t_0 + \frac{h}{2}, x_0 + \frac{k_0}{2}, y_0 + \frac{l_0}{2}\right) & l_1 &= hg\left(t_0 + \frac{h}{2}, x_0 + \frac{k_0}{2}, y_0 + \frac{l_0}{2}\right) \\ k_2 &= hf\left(t_0 + \frac{h}{2}, x_0 + \frac{k_1}{2}, y_0 + \frac{l_1}{2}\right) & l_2 &= hg\left(t_0 + \frac{h}{2}, x_0 + \frac{k_1}{2}, y_0 + \frac{l_1}{2}\right) \\ k_3 &= hf(t_0 + h, x_0 + k_2, y_0 + l_2) & l_3 &= hg(t_0 + h, x_0 + k_2, y_0 + l_2) \end{aligned}$$

and

$$\begin{aligned} x_1 &= x_0 + \frac{1}{6}(k_0 + 2k_1 + 2k_2 + k_3) \\ y_1 &= y_0 + \frac{1}{6}(l_0 + 2l_1 + 2l_2 + l_3) \end{aligned}$$

To continue the computation, replace  $t_0$ ,  $x_0$ , and  $y_0$  in the above formulas by  $t_1 = t_0 + h$ ,  $x_1$ , and  $y_1$  just calculated. Extension of this method to more than two equations follows precisely this same pattern.

## 209.9 Numerical Solution of Integral Equations

---

This section considers a method of numerically solving the Fredholm integral equation of the second kind:

$$u(x) = f(x) + \lambda \int_a^b k(x, t)u(t)dt \quad \text{for } u(x)$$

The method discussed arises because a definite integral can be closely approximated by any of several numerical integration formulas (each of which arises by approximating the function by some polynomial over an interval). Thus, the definite integral can be replaced by an integration formula which becomes

$$u(x) = f(x) + \lambda(b-a) \left[ \sum_{i=1}^n c_i k(x, t_i)u(t_i) \right]$$

where  $t_1, \dots, t_n$  are points of subdivision of the  $t$  axis,  $a \leq t \leq b$ , and the  $c$ s are coefficients whose values depend upon the type of numerical integration formula used. Now, this must hold for all values of  $x$ , where  $a \leq x \leq b$ ; so it must hold for  $x = t_1, x = t_2, \dots, x = t_n$ . Substituting for  $x$

successively  $t_1, t_2, \dots, t_n$ , and setting  $u(t_i) = u_i$  and  $f(t_i) = f_i$ , we get  $n$  linear algebraic equations for the  $n$  unknowns  $u_1, \dots, u_n$ . That is,

$$u_i = f_i + (b - a)[c_1 k(t_i, t_1)u_1 + c_2 k(t_i, t_2)u_2 + \dots + c_n k(t_i, t_n)u_n], \quad i = 1, 2, \dots, n$$

These  $u_j$  may be solved for by the methods under the section entitled "Numerical Solution of Linear Equations."

## 209.10 Numerical Methods for Partial Differential Equations

---

The ultimate goal of numerical (discrete) methods for partial differential equations (PDEs) is the reduction of continuous systems (projections) to discrete systems that are suitable for high-speed computer solutions. The user must be cautioned that the seeming elementary nature of the techniques holds pitfalls that can be seriously misleading. These approximations often lead to difficult mathematical questions of adequacy, accuracy, convergence, stability, and consistency. Convergence is concerned with the approach of the approximate numerical solution to the exact solution as the number of mesh units increase indefinitely in some sense. Unless the numerical method can be shown to converge to the exact solution, the chosen method is unsatisfactory.

Stability deals in general with error growth in the calculation. As stated before, any numerical method involves truncation and round-off errors. These errors are not serious unless they grow as the computation proceeds (i.e., the method is unstable).

### Finite Difference Methods

In these methods, the derivatives are replaced by various finite differences. The methods will be illustrated for problems in two space dimensions  $(x, y)$  or  $(x, t)$ , where  $t$  is timelike. Using subdivisions  $\Delta x = h$  and  $\Delta y = k$  with  $u(ih, jk) = u_{i,j}$ , approximate

$$\begin{aligned} u_x|_{i,j} &= [(u_{i+1,j} - u_{i,j})/h] + O(h) \quad (\text{forward difference}), \text{ a first-order } [O(h)] \text{ method, or} \\ u_x|_{i,j} &= [(u_{i+1,j} - u_{i-1,j})/2h] + O(h^2) \quad (\text{central difference}), \text{ a second-order method. The second} \\ &\text{derivative is usually approximated with the second-order method} \\ u_{xx}|_{i,j} &= [(u_{i+1,j} - 2u_{i,j} + u_{i-1,j})/h^2] + O(h^2) \end{aligned}$$

**Example.** Using second-order differences for  $u_{xx}$  and  $u_{yy}$ , the five-point difference equation (with  $h = k$ ) for Laplace's equation  $u_{xx} + u_{yy} = 0$  is  $u_{i,j} = \frac{1}{4}[u_{i+1,j} + u_{i-1,j} + u_{i,j+1} + u_{i,j-1}]$ . The accuracy is  $O(h^2)$ . This model is called *implicit* because one must solve for the total number of unknowns at the unknown grid points  $(i, j)$  in terms of the given boundary data. In this case, the system of equations is a linear system.

**Example.** Using a forward-difference approximation for  $u_t$  and a second-order approximation for  $u_{xx}$ , the diffusion equation  $u_t = u_{xx}$  is approximated by the *explicit* formula  $u_{i,j+1} = ru_{i-1,j} + (1-2r)u_{i,j} + ru_{i+1,j}$ . This classic result permits step-by-step advancement in the  $t$  direction

beginning with the initial data at  $t = 0$  ( $j = 0$ ) and guided by the boundary data. Here, the term  $r = \Delta t / (\Delta x)^2 = k/h^2$  is restricted to be less than or equal to  $1/2$  for stability and the truncation error is  $O(k^2 + kh^2)$ .

The Crank-Nicolson implicit formula which approximates the diffusion equation  $u_t = u_{xx}$  is

$$\begin{aligned} -r\lambda u_{i-1,j+1} + (1 + 2r\lambda)u_{i,j+1} - r\lambda u_{i+1,j+1} &= r(1 - \lambda)u_{i-1,j} \\ &+ [1 - 2r(1 - \lambda)]u_{i,j} \\ &+ r(1 - \lambda)u_{i+1,j} \end{aligned}$$

The stability of this numerical method was analyzed by Crandall [Ames, 1993] where the  $\lambda$ ,  $r$  stability diagram is given.

Approximation of the time derivative in  $u_t = u_{xx}$  by a central difference leads to an always unstable approximation—the useless approximation

$$u_{i,j+1} = u_{i,j-1} + 2r(u_{i+1,j} - 2u_{i,j} + u_{i-1,j})$$

which is a warning to be careful.

The foregoing method is *symmetric* with respect to the point  $(i,j)$ , where the method is centered. Asymmetric methods have some computational advantages, so the Saul'yev method is described [Ames, 1993]. The algorithms ( $r = k/h^2$ )

$$(1 + r)u_{i,j+1} = u_{i,j} + r(u_{i-1,j+1} - u_{i,j} + u_{i+1,j}) \quad (\text{Saul'yev A})$$

$$(1 + r)u_{i,j+1} = u_{i,j} + r(u_{i+1,j+1} - u_{i,j} + u_{i-1,j}) \quad (\text{Saul'yev B})$$

are used as in any one of the following options:

1. Use Saul'yev A only and proceed line-by-line in the  $t(j)$  direction, but *always* from the left boundary on a line.
2. Use Saul'yev B only and proceed line-by-line in the  $t(j)$  direction, but *always* from the right boundary to the left on a line.
3. Alternate from line to line by first using Saul'yev A and then B, or the reverse. This is related to *alternating direction methods*.
4. Use Saul'yev A and Saul'yev B on the same line and average the results for the final answer (A first, and then B). This is equivalent to introducing the dummy variables  $P_{i,j}$  and  $Q_{i,j}$

such that

$$\begin{aligned} (1 + r)P_{i,j+1} &= U_{i,j} + r(P_{i-1,j+1} - U_{i,j} + U_{i+1,j}) \\ (1 + r)Q_{i,j+1} &= U_{i,j} + r(Q_{i+1,j+1} - U_{i,j} + U_{i-1,j}) \end{aligned}$$

and

$$U_{i,j+1} = \frac{1}{2}(P_{i,j+1} + Q_{i,j+1})$$

This averaging method has some computational advantage because of the possibility of truncation error cancellation. As an alternative, one can retain the  $P_{i,j}$  and  $Q_{i,j}$  from the previous step and replace  $U_{i,j}$  and  $U_{i+1,j}$  by  $P_{i,j}$  and  $P_{i+1,j}$ , respectively, and  $U_{i,j}$  and  $U_{i-1,j}$  by  $Q_{i,j}$  and  $Q_{i-1,j}$ , respectively.

## Weighted Residual Methods (WRMs)

To set the stage for the method of finite elements, we briefly describe the WRMs, which have several variations—the interior, boundary, and mixed methods. Suppose the equation is  $Lu = f$ , where  $L$  is the partial differential operator and  $f$  is a known function, of say  $x$  and  $y$ . The first step in WRM is to select a class of known basis functions  $b_i$  (e.g., trigonometric, Bessel, Legendre) to approximate  $u(x,y)$  as  $\sim \sum a_i b_i(x,y) = U(x,y,a)$ . Often, the  $b_i$  are selected so that  $U(x,y,a)$  satisfy the boundary conditions. This is essentially the *interior method*. If the  $b_i$  in  $U(x,y,a)$  are selected to satisfy the differential equations, but not the boundary conditions, the variant is called the *boundary method*. When neither the equation nor the boundary conditions are satisfied, the method is said to be *mixed*. The least ingenuity is required here. The usual method of choice is the interior method.

The second step is to select an optimal set of constants  $a_i$ ,  $i = 1, 2, \dots, n$ , by using the residual  $R_I(U) = LU - f$ . This is done here for the interior method. In the boundary method, there are a set of boundary residual  $R_B$ , and, in the mixed method, both  $R_I$  and  $R_B$ . Using the spatial average  $(w, v) = \int_V w v dV$ , the criterion for selecting the values of  $a_i$  is the requirement that the  $n$  spatial averages

$$(b_i, R_E(U)) = 0, \quad i = 1, 2, \dots, n$$

These represent  $n$  equations (linear if the operator  $L$  is linear and nonlinear otherwise) for the  $a_i$ .

Particular WRMs differ because of the choice of the  $b_j$ s. The most common follow.

1. *Subdomain* The domain  $V$  is divided into  $n$  smaller, not necessarily disjoint, subdomains  $V_j$  with  $w_j(x,y) = 1$  if  $(x,y)$  is in  $V_j$ , and 0 if  $(x,y)$  is not in  $V_j$ .
2. *Collocation* Select  $n$  points  $P_j = (x_j, y_j)$  in  $V$  with  $w_j(P_j) = \delta(P - P_j)$ , where  $\int_V \phi(P) \delta(P - P_j) dP = \phi(P_j)$  for all test functions  $\phi(P)$  which vanish outside the compact set  $V$ . Thus,  $(w_j, R_E) = \int_V \delta(P - P_j) R_E dV = R_E[U(P_j)] \equiv 0$  (i.e., the residual is set equal to zero at the  $n$  points  $P_j$ ).
3. *Least squares* Here, the functional  $I(a) = \int_V R_E^2 dV$ , where  $a = (a_1, \dots, a_n)$ , is to be made stationary with respect to the  $a_j$ . Thus,  $0 = \partial I / \partial a_j = 2 \int_V R_E (\partial R_E / \partial a_j) dV$ , with  $j = 1, 2, \dots, n$ . The  $w_j$  in this case are  $\partial R_E / \partial a_j$ .
4. *Bubnov-Galerkin* Choose  $w_j(P) = b_j(P)$ . This is perhaps the best-known method.

5. *Stationary Functional (Variational) Method* With  $\phi$  a variational integral (or other functional), set  $\partial\phi[U]/\partial a_j = 0$ , where  $j = 1, \dots, n$ , to generate the  $n$  algebraic equations.

**Example.**  $u_{xx} + u_{yy} = -2$ , with  $u = 0$  on the boundaries of the square  $x = \pm 1, y = \pm 1$ . Select an interior method with  $U = a_1(1 - x^2)(1 - y^2) + a_2x^2y^2(1 - x^2)(1 - y^2)$ , whereupon the residual  $R_E(U) = -2a_1(2 - x^2 - y^2) + 2a_2[(1 - 6x^2)y^2(1 - y^2) + (1 - 6y^2)x^2(1 - x^2)] + 2$ . Collocating at  $(\frac{1}{3}, \frac{1}{3})$  and  $(\frac{2}{3}, \frac{2}{3})$  gives the two linear equations  $-32a_1/9 + 32a_2/243 + 2 = 0$  and  $-20a_1/9 - 400a_2/243 + 2 = 0$  for  $a_1$  and  $a_2$ .

WRM methods can obviously be used as approximate methods. We have now set the stage for *finite elements*.

## Finite Elements

The WRM methods are more general than the *finite element* (FE) methods. FE methods require, in addition, that the basis functions be finite elements (i.e., functions that are zero except on a small part of the domain under consideration). A typical example of an often used basis is that of triangular elements. For a triangular element with Cartesian coordinates  $(x_1, y_1)$ ,  $(x_2, y_2)$ , and  $(x_3, y_3)$ , define natural coordinates  $L_1, L_2$ , and  $L_3$  ( $L_i \leftrightarrow (x_i, y_i)$ ) so that  $L_i = A_i/A$  where

$$A = \frac{1}{2} \det \begin{bmatrix} 1 & x_1 & y_1 \\ 1 & x_2 & y_2 \\ 1 & x_3 & y_3 \end{bmatrix}$$

is the area of the triangle and

$$A_1 = \frac{1}{2} \det \begin{bmatrix} 1 & x & y \\ 1 & x_2 & y_2 \\ 1 & x_3 & y_3 \end{bmatrix}$$

$$A_2 = \frac{1}{2} \det \begin{bmatrix} 1 & x_1 & y_1 \\ 1 & x & y \\ 1 & x_3 & y_3 \end{bmatrix}$$

$$A_3 = \frac{1}{2} \det \begin{bmatrix} 1 & x_1 & y_1 \\ 1 & x_2 & y_2 \\ 1 & x & y \end{bmatrix}$$

Clearly  $L_1 + L_2 + L_3 = 1$ , and the  $L_i$  are one at node  $i$  and zero at the other nodes. In terms of the Cartesian coordinates,

$$\begin{bmatrix} L_1 \\ L_2 \\ L_3 \end{bmatrix} = \frac{1}{2A} \begin{bmatrix} x_2 y_3 - x_3 y_2, & y_2 - y_3, & x_3 - x_2 \\ x_3 y_1 - x_1 y_3, & y_3 - y_1, & x_1 - x_3 \\ x_1 y_2 - x_2 y_1, & y_1 - y_2, & x_2 - x_1 \end{bmatrix} \begin{bmatrix} 1 \\ x \\ y \end{bmatrix}$$

is the linear triangular element relation.

Tables of linear, quadratic, and cubic basis functions are given in the literature. Notice that while the linear basis needs three nodes, the quadratic requires six and the cubic basis ten. Various modifications, such as the Hermite basis, are described in the literature. Triangular elements are useful in approximating irregular domains.

For rectangular elements, the *chapeau* functions are often used. Let us illustrate with an example. Let  $u_{xx} + u_{yy} = Q$ ,  $0 < x < 2$ ,  $0 < y < 2$ ,  $u(x, 2) = 1$ ,  $u(0, y) = 1$ ,  $u_y(x, 0) = 0$ ,  $u_x(2, y) = 0$ , and  $Q(x, y) = Q_w \delta(x - 1) \delta(y - 1)$ ,

$$\delta(x) = \begin{cases} 0 & x \neq 0 \\ 1 & x = 0 \end{cases}$$

Using four equal rectangular elements, map the element  $I$  with vertices at (0,0), (0,1), (1,1), and (1,0) into the local (canonical) coordinates  $(\xi, \eta)$ ,  $-1 \leq \xi \leq 1$ ,  $-1 \leq \eta \leq 1$ , by means of  $x = \frac{1}{2}(\xi + 1)$ ,  $y = \frac{1}{2}(\eta + 1)$ . This mapping permits one to develop software that standardizes the treatment of all elements. Converting to  $(\xi, \eta)$  coordinates, our problem becomes  $u_{\xi\xi} + u_{\eta\eta} = \frac{1}{4}Q$ ,  $-1 \leq \xi \leq 1$ ,  $-1 \leq \eta \leq 1$ ,  $Q = Q_w \delta(\xi - 1) \delta(\eta - 1)$ .

First, a trial function  $\bar{u}(\xi, \eta)$  is defined as  $u(\xi, \eta) \approx \bar{u}(\xi, \eta) = \sum_{j=1}^4 A_j \phi_j(\xi, \eta)$  (in element  $I$ ) where the  $\phi_j$  are the two-dimensional chapeau functions

$$\begin{aligned} \phi_1 &= \left[ \frac{1}{2}(1 - \xi) \frac{1}{2}(1 - \eta) \right] & \phi_2 &= \left[ \frac{1}{2}(1 + \xi) \frac{1}{2}(1 - \eta) \right] \\ \phi_3 &= \left[ \frac{1}{2}(1 + \xi) \frac{1}{2}(1 + \eta) \right] & \phi_4 &= \left[ \frac{1}{2}(1 - \xi) \frac{1}{2}(1 + \eta) \right] \end{aligned}$$

Clearly  $\phi_i$  take the value one at node  $i$ , provide a bilinear approximation, and are nonzero only over elements adjacent to node  $i$ .

Second, the equation residual  $R_E = \nabla^2 \bar{u} - \frac{1}{4}Q$  is formed and a WRM procedure is selected to formulate the algebraic equations for the  $A_i$ . This is indicated using the Galerkin method. Thus, for element  $I$ , we have

$$\int \int_{D_I} (\bar{u}_{\xi\xi} + \bar{u}_{\eta\eta} - Q) \phi_i(\xi, \eta) d\xi d\eta = 0, \quad i = 1, \dots, 4$$

Applying Green's theorem, this result becomes

$$\int \int_{D_I} [\bar{u}_{\xi}(\phi_i)_{\xi} + \bar{u}_{\eta}(\phi_i)_{\eta} + \frac{1}{4}Q \phi_i] d\xi d\eta - \int_{\partial D_I} (\bar{u}_{\xi} c_{\xi} + \bar{u}_{\eta} c_{\eta}) \phi_i ds = 0, \quad i = 1, 2, \dots, 4$$

Using the same procedure in all four elements and recalling the property that the  $\phi_i$  in each element are nonzero only over elements adjacent to node  $i$  gives the following nine equations:

$$\sum_{e=1}^4 \left\{ \int_{D_e} \sum_{j=1}^9 A_j [(\phi_j)_\xi (\phi_i)_\xi + (\phi_j)_\eta (\phi_i)_\eta] + \frac{1}{4} Q \phi_i \right\} d\xi d\eta - \sum_{e=1}^4 \int_{\partial D_e} (\bar{u}_\xi c_\xi + \bar{u}_\eta c_\eta) \phi ds = 0, \quad i = 1, 2, \dots, 9$$

where the  $c_\xi$  and  $c_\eta$  are the direction cosines of the appropriate element ( $e$ ) boundary.

## Method of Lines

The *method of lines*, when used on PDEs in two dimensions, reduces the PDE to a system of ordinary differential equations (ODEs), usually by finite difference or finite element techniques. If the original problem is an initial value (boundary value) problem, then the resulting ODEs form an initial value (boundary value) problem. These ODEs are solved by ODE numerical methods.

**Example.**  $u_t = u_{xx} + u^2$ ,  $0 < x < 1$ ,  $0 < t$ , with the initial value  $u(x,0) = x$ , and boundary data  $u(0,t) = 0$ ,  $u(1,t) = \sin t$ . A discretization of the space variable ( $x$ ) is introduced and the time variable is left continuous. The approximation is  $\dot{u}_i = (u_{i+1} - 2u_i + u_{i-1})/h^2 + u_i^2$ . With  $h = 1/5$ , the equations become

$$\begin{aligned} u_0(t) &= 0 \\ \dot{u}_1 &= \frac{1}{25}[u_2 - 2u_1] + u_1^2 \\ \dot{u}_2 &= \frac{1}{25}[u_3 - 2u_2 + u_1] + u_2^2 \\ \dot{u}_3 &= \frac{1}{25}[u_4 - 2u_3 + u_2] + u_3^2 \\ \dot{u}_4 &= \frac{1}{25}[\sin t - 2u_4 + u_3] + u_4^2 \\ u_5 &= \sin t \end{aligned}$$

and  $u_1(0) = 0.2$ ,  $u_2(0) = 0.4$ ,  $u_3(0) = 0.6$ , and  $u_4(0) = 0.8$ .

## 209.11 Discrete and Fast Fourier Transforms

Let  $x(n)$  be a sequence that is nonzero only for a finite number of samples in the interval  $0 \leq n \leq N - 1$ . The quantity

$$X(k) = \sum_{n=0}^{N-1} x(n)e^{-i(2\pi/N)nk}, \quad k = 0, 1, \dots, N-1$$

is called the *discrete Fourier transform* (DFT) of the sequence  $x(n)$ . Its inverse (IDFT) is given by

$$x(n) = \frac{1}{N} \sum_{k=0}^{N-1} X(k)e^{i(2\pi/N)nk}, \quad n = 0, 1, \dots, N-1 \quad (i^2 = -1)$$

Clearly, DFT and IDFT are finite sums and there are  $N$  frequency values. Also,  $X(k)$  is periodic in  $k$  with period  $N$ .

**Example.**  $x(0) = 1, x(1) = 2, x(2) = 3, x(3) = 4$

$$X(k) = \sum_{n=0}^3 x(n)e^{-i(2\pi/4)nk}, \quad k = 0, 1, 2, 3, 4$$

Thus,

$$X(0) = \sum_{n=0}^3 x(n) = 10$$

and  $X(1) = x(0) + x(1)e^{-i\pi/2} + x(2)e^{-i\pi} + x(3)e^{-i3\pi/2} = 1 - 2i - 3 + 4i = -2 + 2i$ ;  $X(2) = -2$ ;  $X(3) = -2 - 2i$ .

## DFT Properties

1. **Linearity:** If  $x_3(n) = ax_1(n) + bx_2(n)$ , then  $X_3(k) = aX_1(k) + bX_2(k)$ .
2. **Symmetry:** For  $x(n)$  real,  $\text{Re}[X(k)] = \text{Re}[X(N-k)]$ ,  $\text{Im}[X(k)] = -\text{Im}[X(N-k)]$ .
3. **Circular shift:** By a circular shift of a sequence defined in the interval  $0 \leq n \leq N-1$ , we mean that, as values *fall off* from one end of the sequence, they are appended to the other end. Denoting this by  $x(n \oplus m)$ , we see that positive  $m$  means shift left and negative  $m$  means shift right. Thus,  $x_2(n) = x_1(n \oplus m) \Leftrightarrow X_2(k) = X_1(k)e^{i(2\pi/N)km}$ .
4. **Duality:**  $x(n) \Leftrightarrow X(k)$  implies  $(1/N)X(n) \Leftrightarrow x(-k)$ .
5. **Z-transform relation:**  $X(k) = X(z)|_{z=e^{i(2\pi/N)k}}, k = 0, 1, \dots, N-1$ .
6. **Circular convolution:**  $x_3(n) = \sum_{m=0}^{N-1} x_1(m)x_2(n \ominus m) = \sum_{\ell=0}^{N-1} x_1(n \ominus \ell)x_2(\ell)$  where  $x_2(n \ominus m)$  corresponds to a circular shift to the right for positive  $m$ .

One fast algorithm for calculating DFTs is the radix-2 *fast Fourier transform* developed by J. W. Cooley and J. W. Tucker. Consider the two-point DFT  $X(k) = \sum_{n=0}^1 x(n)e^{-i(2\pi/2)nk}, k = 0, 1$ . Clearly,  $X(k) = x(0) + x(1)e^{-i\pi k}$ . So,  $X(0) = x(0) + x(1)$  and  $X(1) = x(0) - x(1)$ . This process can be extended to DFTs of length  $N = 2^r$ , where  $r$  is a positive integer. For  $N = 2^r$ , decompose the  $N$ -point DFT into *two*  $N/2$ -point DFTs. Then, decompose each  $N/2$ -point DFT into *two*  $N/4$ -point DFTs, and so on until eventually we have  $N/2$  *two*-point DFTs. Computing these as indicated above, we recombine them into  $N/4$  four-point DFTs and then  $N/8$  eight-point DFTs, and so on, until the DFT is computed. The total number of DFT operations (for large  $N$ ) is  $O(N^2)$ , and that of the FFT is  $O(N \log_2 N)$ , quite a saving for large  $N$ .

Figure 3

### THE OREGONATOR

The "Oregonator" is a periodic chemical reaction describable by three nonlinear first-order differential equations. The results (Fig. 1) illustrate the periodic nature of the major chemical versus time. Figure 2 shows the phase diagram of two of the reactants, and Fig. 3 is the three-dimensional phase diagram of all reactants. The numerical computation was done using a fourth-order Runge-Kutta method on Mathematica by Waltraud Rufeger at the Georgia Institute of Technology.

## 209.12 Software

---

Some available software is listed here.

### General Packages

General software packages include Maple, Mathematica, and Matlab. All contain algorithms for handling a large variety of both numerical and symbolic computations.

### Special Packages for Linear Systems

In the IMSL Library, there are three complementary linear system packages of note.

LINPACK is a collection of programs concerned with *direct* methods for general (or full) symmetric, symmetric positive definite, triangular, and tridiagonal matrices. There are also programs for least squares problems, along with the QR algorithm for eigensystems and the singular value decompositions of rectangular matrices. The programs are intended to be completely machine independent, fully portable, and run with good efficiency in most computing environments. The LINPACK User's Guide by Dongarra *et al.* is the basic reference.

ITPACK is a modular set of programs for iterative methods. The package is oriented toward the sparse matrices that arise in the solution of PDEs and other applications. While the programs apply to full matrices, that is rarely profitable. Four basic iteration methods and two convergence acceleration methods are in the package. There is a Jacobi, SOR (with optimum relaxation parameter estimated), symmetric SOR, and reduced system (red-black ordering) iteration, each with semi-iteration and conjugate gradient acceleration. All parameters for these iterations are automatically estimated. The practical and theoretical background for ITPACK is found in Hagemen and Young [1981].

YALEPACK is a substantial collection of programs for sparse matrix computations.

### Ordinary Differential Equations Packages

Also in IMSL, one finds such sophisticated software as DVERK, DGEAR, or DREBS for initial value problems. For two-point boundary value problems, one finds DTPTB (use of DVERK and multiple shooting) or DVCPR.

## Partial Differential Equations Packages

DISPL was developed and written at Argonne National Laboratory. DISPL is designed for nonlinear second-order PDEs (parabolic, elliptic, hyperbolic (some cases), and parabolic-elliptic). Boundary conditions of a general nature and material interfaces are allowed. The spatial dimension can be either one or two and in Cartesian, cylindrical, or spherical (one dimension only) geometry. The PDEs are reduced to ordinary DEs by Galerkin discretization of the spatial variables. The resulting ordinary DEs in the timelike variable are then solved by an ODE software package (such as GEAR). Software features include graphics capabilities, printed output, dump/restart facilities, and free format input. DISPL is intended to be an engineering and scientific tool and is not a finely tuned production code for a small set of problems. DISPL makes no effort to control the spatial discretization errors. It has been used to successfully solve a variety of problems in chemical transport, heat and mass transfer, pipe flow, etc.

PDELIB was developed and written at Los Alamos Scientific Laboratory. PDELIB is a library of subroutines to support the numerical solution of evolution equations with a timelike variable and one or two space variables. The routines are grouped into a dozen independent modules according to their function (i.e., accepting initial data, approximating spatial derivatives, advancing the solution in time). Each task is isolated in a distinct module. Within a module, the basic task is further refined into general-purpose flexible lower-level routines. PDELIB can be understood and used at different levels. Within a small period of time, a large class of problems can be solved by a novice. Moreover, it can provide a wide variety of outputs.

DSS/2 is a differential systems simulator developed at Lehigh University as a transportable numerical method of lines (NMOL) code. See also LEANS.

FORSIM is designed for the automated solution of sets of implicitly coupled PDEs of the form

$$\frac{\partial u_i}{\partial t} = \phi_i(x, t, u_i, u_j, \dots, (u_i)_x, \dots, (u_i)_{xx}, (u_j)_{xx}, \dots), \quad \text{for } i = 1, \dots, N$$

The user specifies the  $\phi_i$  in a simple FORTRAN subroutine. Finite difference formulas of any order may be selected for the spatial discretization and the spatial grid need not be equidistant. The resulting system of time-dependent ODEs is solved by the method of lines.

SLDGL is a program package for the self-adaptive solution of nonlinear systems of elliptic and parabolic PDEs in up to three space dimensions. Variable step size and variable order are permitted. The discretization error is estimated and used for the determination of the optimum grid and optimum orders. This is the most general of the codes described here (not for hyperbolic systems, of course). This package has seen extensive use in Europe.

FIDISOL (finite difference solver) is a program package for nonlinear systems of two- or three-dimensional elliptic and parabolic systems in rectangular domains or in domains that can be transformed analytically to rectangular domains. This package is actually a redesign of parts of SLDGL, primarily for the solution of large problems on vector computers. It has been tested on the CYBER 205, CRAY-1M, CRAY X-MP/22, and VP 200. The program vectorizes very well and uses the vector arithmetic efficiently. In addition to the numerical solution, a reliable error estimate is computed.

CAVE is a program package for conduction analysis via eigenvalues for three-dimensional geometries using the method of lines. In many problems, much time is saved because only a few terms suffice.

Many industrial and university computing services subscribe to the IMSL Software Library. Announcements of new software appear in *Directions*, a publication of IMSL. A brief description of some IMSL packages applicable to PDEs and associated problems is now given. In addition to those packages just described, two additional software packages bear mention. The first of these, the ELLPACK system, solves elliptic problems in two dimensions with general domains and in three dimensions with box-shaped domains. The system contains over 30 numerical methods modules, thereby providing a means of evaluating and comparing different methods for solving elliptic problems. ELLPACK has a special high-level language making it easy to use. New algorithms can be added or deleted from the system with ease.

Second, TWODEPEP is IMSL's general finite element system for two-dimensional elliptic, parabolic, and eigenvalue problems. The Galerkin finite elements available are triangles with quadratic, cubic, or quartic basic functions, with one edge curved when adjacent to a curved boundary, according to the isoparametric method. Nonlinear equations are solved by Newton's method, with the resulting linear system solved directly by Gauss elimination. PDE/PROTRAN is also available. It uses triangular elements with piecewise polynomials of degree 2, 3, or 4 to solve quite general steady state, time-dependent, and eigenvalue problems in general two-dimensional regions. There is a simple user input. Additional information may be obtained from IMSL. NASTRAN and STRUDL are two advanced finite element computer systems available from a variety of sources. Another, UNAFEM, has been extensively used.

## 210.1 Units and Variables

## 210.2 Method of Dimensions

**William F. Ames***Georgia Institute of Technology***210.1 Units and Variables**

Dimensional analysis is a mathematical tool whose use will enable the scientist and engineer to save time in planning experiments and correlating results of experiments. The method arose in the science of mechanics. In this science three *units* are regarded as *fundamental*, namely, *length*, *mass*, and *time*. Other employed units are called derived units. For example, velocity and acceleration are derived units defined by reference to the two fundamental units—length and time. The units of force-momentum, mechanical energy, and power—are dependent on all three of the fundamental units. The study of electricity, heat transfer, and so forth requires the inclusion of other fundamental units such as charge.

Here the fundamental units adopted are *length* (in centimeters),  $L$ ; *mass* (in grams),  $M$ ; and *time* (in seconds),  $T$ . This is the CGS system of units. Others are the British, or foot, pound, second (FPS), system and the MKS system, which is closely allied to the CGS system. With the CGS system the dimensional formulas of some basic physical *variables* are given in [Tables 210.1](#) through [210.3](#).

**Table 210.1** Dimensional Physical Quantities

Physical Quantity	Exponents of Dimensions			Formula
	$L$	$M$	$T$	
Volume density	−3	1	0	$L^{-3} M$
Length per unit volume	−2	0	0	$L^{-2}$
Area density	−2	1	0	$L^{-2} M$
Curvature	−1	0	0	$L^{-1}$
Linear density	−1	1	0	$L^{-1} M$
Angle	0	0	0	
Mass	0	1	0	$M$
Length	1	0	0	$L$

Mass $\times$ length	1	1	0	$LM$
Area	2	0	0	$L^2$
Moment of inertia	2	1	0	$L^2 M$
Volume	3	0	0	$L^3$
Speed of density change	-3	1	-1	$L^{-3} MT^{-1}$
Velocity per unit volume	-2	0	-1	$L^{-2} T^{-1}$
Momentum per unit volume	-2	1	-1	$L^{-2} MT^{-1}$
Velocity per unit area	-1	0	-1	$L^{-1} T^{-1}$
Viscosity	-1	1	-1	$L^{-1} MT^{-1}$
Frequency	0	0	-1	$T^{-1}$
Mass per second	0	1	-1	$MT^{-1}$
Velocity	1	0	-1	$LT^{-1}$
Momentum	1	1	-1	$LMT^{-1}$
Kinematic viscosity	2	0	-1	$L^2 T^{-1}$
Action	2	1	-1	$L^2 MT^{-1}$
Volume per second	3	0	-1	$L^3 T^{-1}$
Acceleration of density change	-3	1	-2	$L^{-3} MT^{-2}$
Acceleration per unit volume	-2	0	-2	$L^{-2} T^{-2}$
Force per unit volume	-2	1	-2	$L^{-2} MT^{-2}$
Acceleration per unit area	-1	-0	-2	$L^{-1} T^{-2}$
Pressure	-1	1	-2	$L^{-1} MT^{-2}$
Angular acceleration	0	0	-2	$T^{-2}$
Surface tension	0	1	-2	$MT^{-2}$
Acceleration	1	0	-2	$LT^{-2}$
Force	1	1	-2	$LMT^{-2}$
Temperature	2	0	-2	$L^2 T^{-2}$
Energy, torque	2	1	-2	$L^2 MT^{-2}$
Rate of change of volume per second	3	0	-2	$L^3 T^{-2}$
Power	2	1	-3	$L^2 MT^{-3}$

**Table 210.2** Dimensional Thermal Quantities

Physical Quantity	Thermal Units	Dynamic Units
Temperature	$\theta$	$\theta$
Quantity of heat	$H$	$L^2 MT^{-2}$
Specific heat	Dimensionless	Dimensionless
Heat capacity per unit mass	$L^0 M^{-1} T^0 H \theta^{-1}$	$L^2 M^0 T^{-2} \theta^{-1}$
Heat capacity per unit volume	$L^{-3} M^0 T^0 H \theta^{-1}$	$L^{-1} MT^{-2} \theta^{-1}$
Temperature gradient	$L^{-1} M^0 T^0 H^0 \theta^{-1}$	$L^{-1} M^0 T^0 \theta^{-1}$
Conductivity	$L^{-1} M^0 T^{-1} H^0 \theta^{-1}$	$LMT^{-3} \theta^{-1}$
Entropy	$H \theta^{-1}$	$L^2 MT^{-2} \theta^{-1}$

**Table 210.3** Dimensional Magnetic and Electrical Quantities

Physical Quantity	Electromagnetic	Electrostatic
Magnetic pole, $P$	$L^{3/2} M^{1/2} T^{-1} \mu^{1/2}$	$L^{1/2} M^{1/2} T^0 \kappa^{-1/2}$
Strength of magnetic field, $H$	$L^{-1/2} M^{1/2} T^{-1} \mu^{-1/2}$	$L^{1/2} M^{1/2} T^{-2} \kappa^{1/2}$
Magnetic and electric induction, $\mu H, \kappa E$	$L^{-1/2} M^{1/2} T^{-1} \mu^{1/2}$	$L^{-1/2} M^{1/2} T^{-1} \kappa^{1/2}$
Magnetic and electric moments, $PL, QL$	$L^{5/2} M^{1/2} T^{-1} \mu^{1/2}$	$L^{5/2} M^{1/2} T^{-1} \kappa^{1/2}$
Electric current, $I$	$L^{1/2} M^{1/2} T^{-1} \mu^{-1/2}$	$L^{3/2} M^{1/2} T^{-2} \kappa^{1/2}$
Quantity of electricity, $Q$	$L^{1/2} M^{1/2} T^0 \mu^{-1/2}$	$L^{3/2} M^{1/2} T^{-1} \kappa^{1/2}$
Potential difference, $E$	$L^{3/2} M^{1/2} T^{-2} \mu^{1/2}$	$L^{1/2} M^{1/2} T^{-1} \kappa^{-1/2}$
Resistance, $R$	$LM^0 T^{-1} \mu$	$L^{-1} M^0 T \kappa^{-1}$
Capacitance, $C$	$L^{-1} M^0 T^2 \mu^{-1}$	$LM^0 T^0 \kappa$
Inductance, $ET/I$	$LM^0 T^0 \mu$	$L^{-1} M^0 T^2 \kappa^{-1}$
Permeability, $\mu$	$L^0 M^0 T^0 \mu$	$L^{-2} M^0 T^2 \kappa^{-1}$
Permittivity, $\kappa$	$L^{-2} M^0 T^2 \mu^{-1}$	$L^0 M^0 T^0 \kappa$

Some *variables* are dimensionless. For example, angle is defined as arc/radius; strain as volume/volume; and specific gravity as density/density (dimensions  $(L^{-3} M)/(L^{-3} M) = L^0 M^0$ ). In addition there are dimensional constants:  $c$ , the velocity of light in a vacuum, has dimensions  $LT^{-1}$ , and  $g$ , the gravitational constant, has dimensions  $L^3 M^{-1} T^{-2}$ . Some dimensionless constants also appear. An example is the Reynolds number  $N_{\text{Re}} = Dv\rho/\mu$  ( $D$  is diameter), which has dimensions  $(L \cdot LT^{-1} \cdot L^{-3} M)/(L^{-1} MT^{-1}) = L^0 M^0 T^0$ . Some dimensionless groups are listed in Table 210.4.

**Table 210.4** Dimensionless Groups in Engineering

Biot number	$N_{\text{Bi}}$	$hL/k$
Condensation number	$N_{\text{Co}}$	$(h/k)(\mu^2/\rho^2 g)^{1/3}$
Number used in condensation of vapors	$N_{\text{Cv}}$	$L^3 \rho^2 g \lambda / \kappa \mu \Delta t$
Euler number	$N_{\text{Eu}}$	$g_e(-dp)/\rho V^2$
Fourier number	$N_{\text{Fo}}$	$k\theta/\rho c L^2$
Froude number	$N_{\text{Fr}}$	$V^2/Lg$
Graetz number	$N_{\text{Gz}}$	$wc/kL$
Grashof number	$N_{\text{Gr}}$	$L^3 \rho^2 \beta g \Delta t / \mu^2$
Mach number	$N_{\text{Ma}}$	$V/V_a$
Nusselt number	$N_{\text{Nu}}$	$hD/k$
Peclet number	$N_{\text{Pe}}$	$DV\rho c/k$
Prandtl number	$N_{\text{Pr}}$	$c\mu/k$
Reynolds number	$N_{\text{Re}}$	$DV\rho/\mu$
Schmidt number	$N_{\text{Sc}}$	$\mu/\rho D_v$
Stanton number	$N_{\text{St}}$	$h/cV\rho$
Weber number	$N_{\text{We}}$	$LV^2\rho/\sigma g_e$

## 210.2 Method of Dimensions

The *method of dimensions* is based on the simple observation that the dimensions on both sides of an equation must be the same. To illustrate, suppose we wish to find the distance  $s$  traveled in a given time by a particle of mass  $m$  falling from rest under the uniform acceleration due to gravity  $g$ . Assuming  $s = f(g, t, m) = Cg^a t^b m^c$ , where  $C$  is an unknown dimensionless constant and the indices  $a$ ,  $b$ , and  $c$  are to be determined. Examining the dimensions in a dimensional formula we have

$$L = (LT^{-2})^a T^b M^c$$

Clearly  $a = 1$ ,  $b = 2$ , and  $c = 0$ , so  $s = Cgt^2$ . It is not within the realm of dimensional analysis to evaluate  $C$ .

Another example is the two-body problem of astronomy. Suppose a planet of mass  $m$  rotates about the sun (mass  $\overline{M}$ ) in an orbit that is an ellipse of major diameter  $D$ . The physical quantities that will affect the sought-for period,  $t$ , appear to be the mass of the sun, the mass of the planet, the diameter  $D$ , and the gravitational constant  $G$ . Thus we try  $t = C\overline{M}^a m^b D^c G^d + (\text{similar terms})$ , where the similar terms must have the same dimensions, that is, 0 in length, 0 in mass, and 1 in time. The dimensional equation becomes  $T = M^a M^b L^c (L^3 M^{-1} T^{-2})^d$ . Hence

$$0 = c + 3d \quad (\text{length})$$

$$0 = a + b - d \quad (\text{mass})$$

$$1 = -2d \quad (\text{time})$$

The solution of this system is  $d = -\frac{1}{2}$ ,  $c = \frac{3}{2}$ ,  $a$  arbitrary, and  $b = -\frac{1}{2} - a$ . Therefore  $t = C\overline{M}^a m^{(-1/2)-a} D^{3/2} G^{-1/2}$  or  $t^2 = C'(\overline{M}/m)^{2a} (D^3/Gm)$ , which is Kepler's law (the square of the period of a planet is proportional to the cube of the major axis of the orbit). The constants  $C'$  and  $a$  must be evaluated by experiment.

Many other examples are found in the literature. This section is closed with the determination of the height,  $h$ , that a liquid rises in a capillary tube. The relevant equation is  $h = C \cdot \rho^a r^b s^c g^d \theta^e$ , where  $\rho$  is the fluid density,  $r$  is the radius of the tube,  $s$  is the surface tension of the fluid,  $g$  is the acceleration of gravity, and  $\theta$  is the contact angle. The dimensional equation becomes  $L = (L^{-3} M)^a L^b (MT^{-2})^c (LT^{-2})^d$ , which gives rise to the following three linear equations:

$$1 = -3a + b + d \quad (\text{length})$$

$$0 = a + c \quad (\text{mass})$$

$$0 = -2c - 2d \quad (\text{time})$$

in the four unknowns  $a$ ,  $b$ ,  $c$ , and  $d$ . We may express any three of the unknowns in terms of the fourth. Choosing  $a$  we find  $c = -a$ ,  $d = a$ , and  $b = 1 + 2a$ , so  $h = cr(r^2\rho g/s)^a$ . Experiments show that  $h$  is inversely proportional to  $r$ , so that  $a = -1$ . Thus  $h = C(s/r\rho g)$ .

- 211.4 Continuum Volume Visualization
- 211.5 Animation over Time
- 211.6 Summary

**Richard S. Gallagher**

*R. S. Gallagher and Associates*

Visualization is the process of seeing something. In the computer graphics field, the term *visualization* has a more specific meaning, and refers to computational techniques to display and understand behavior. The field of computer graphics visualization is still young; much of its fundamental work took place in the late 1980s. Today, it has grown to become one of the key commercial applications of computer graphics. Key technical aspects of computer graphics visualization include the display of objects in 3-D; display of scalar, vector, and tensor quantities; continuum volume display techniques; and animation over time.

## 211.1 The Display of Objects in 3-D

---

Most modern computer graphics equipment uses display technology similar to that of television, where a two-dimensional array of dots known as **pixels** have individual dot colors set to produce a composite image. Turning data into such a screen image involves representing the data as geometric components, such as lines or polygons, *transforming* these components to a particular view from the observer, coloring or *rendering* these components, and converting them to dots on the screen through a process known as **scan conversion**.

Transformations are generally performed through matrix multiplication of the coordinates of each component, effecting operations including *rotation*, *scaling*, and *translation*. The transformation of a point  $P$  to its transformed position  $P'$  takes the form:

$$[P'] = [T][P] = [r][s][t][P]$$

Scaling and translation matrices can be combined in the form:

$$\begin{bmatrix} s_x & 0 & 0 & \Delta x \\ 0 & s_y & 0 & \Delta y \\ 0 & 0 & s_z & \Delta z \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

which multiplies the vector  $[x, y, z, W]$ , with the fourth element being a nonzero *homogenous coordinate* factor of  $x, y$ , and  $z$ . The rotational transformation is added by multiplying this matrix by matrices corresponding to rotations about the  $x, y$ , and  $z$  axes:

$$\begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & \cos \theta & -\sin \theta & 0 \\ 0 & \sin \theta & \cos \theta & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} \cos \theta & 0 & \sin \theta & 0 \\ 0 & 1 & 0 & 0 \\ -\sin \theta & 0 & \cos \theta & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} \cos \theta & -\sin \theta & 0 & 0 \\ \sin \theta & \cos \theta & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

Other transformations include the simulation of *perspective*, which reduces the  $x$  and  $y$  coordinates in the current view as a function of the  $z$  coordinate, and *clipping*, which removes portions of components intersected by either screen boundaries or an arbitrary *clipping plane*.

Rendering techniques generally involve setting a color or color function across each component, often based on the effects of a light source from the observer to the screen. For example, a square polygon facing the observer may be red, while its color may change towards darker shades of red as the polygon is rotated, becoming completely dark when 90 degrees from the observer. Shading techniques may compute color as a continuous function across a component. Gouraud shading, for example, interpolates a color value across a polygon from its corner values, while another technique known as Phong shading computes color from an interpolation of the light source vector itself across the polygon. More advanced rendering techniques include **ray tracing**, which computes the behavior of light rays to simulate effects such as reflectance, shadows, and translucency, and *texture mapping*, which simulates a pattern or image across surfaces of the displayed model.

## 211.2 Scalar Display Techniques

---

One of the fundamental operations of visualization is the display of a single variable in space. Some of the visual techniques for displaying scalar field values include:

*Color coding* The outside visible surfaces of a model are color-coded with values corresponding to the scalar value (Fig. 211.1). For example, a structural model may have elements of high stress colored red, and low stress colored blue.

*Isovalue display* An **isovalue** is a region of constant scalar value. In the general case, an isovalue can be idealized as a point in one-dimensional space, a curve in two dimensions, and a surface in three dimensions (Fig. 211.2). One particular form of isovalue display, the *contour plot*, displays bands of color on model surfaces corresponding to ranges of isovalues.

Isosurfaces are surfaces of constant 3-D scalar value.

*Particle displays and implicit isovalues* A color-coded distribution of particles within a 3-D

scalar field gives an overview of values throughout the field and can be useful in situations where isosurfaces obscure portions of the interior model. Another application of particle display is to compute and display particles at points corresponding to a particular scalar value. As the density of such particles increases, the resulting image approaches the isosurface of the scalar value in the limit.

**Figure 211.1** Contour representation of a scalar value.

**Figure 211.2** Isosurfaces of a scalar value.

## 211.3 Vector and Tensor Field Display

---

The comprehensible display of multidimensional quantities remains a key area of visualization research. Particular applications include the display of flow fields, multivariate field analysis problems, and examination of derived quantities such as gradients. Some of the current techniques used in vector and tensor field display include:

*Vector and tensor symbols* Symbols, often known as **glyphs**, use size, shape and color to show multiple values at a point in space. For example, a three-pointed triad may have each point colored and sized according to the value of different quantities at that point. More complex glyphs may vary the shape, direction, and color of multiple components to show complex states of behavior, such as the state of a tensor field.

*Vector and tensor field curves* Path curves can be created through a vector or tensor field, generally representing the path of a vector quantity from specified starting locations. Further dimensions of information can be displayed across these path curves by varying quantities such as color, thickness, and cross-sectional geometry.

*Particle field display* A distribution of particles within a field can represent a multivariate quantity by varying attributes such as particle density, color, size, and shape. As one example, [Fig. 211.3](#) shows a particle distribution whose density varies by the gradient, or rate of change, of a state of stress in the Cartesian  $x$ ,  $y$ , and  $z$  directions.

**Figure 211.3** Particle representation of the gradient of a scalar value. Dot color varies by scalar value, while dot density varies by gradient.

All of these techniques share a common approach of combining several visual techniques within a single image to display multivariate behavior. In addition, the use of animation (discussed below) adds the dimension of time and motion to evaluating complex behavior visually.

## 211.4 Continuum Volume Visualization

---

A three-dimensional field, particularly a sampled field such as a medical image, can be represented as a field of volume elements or **voxels**. These voxels can be viewed as tiny cubes connecting a regular array of sample points within the volume. Continuum volume visualization techniques generate imagery by performing operations on the voxel field. Such algorithms can allow an entire scalar-valued field to be represented within a single image, using techniques such as translucency and color variation, and can also provide a more accurate means of computing discrete images, such as isosurfaces (Fig. 211.4). Above all, a voxel representation of a volume keeps an entire volumes data in a form suited to direct visualization and analysis.

**Figure 211.4** Isovalues of density within a voxel dataset.

Many voxel-based techniques operate in either *image space* or *voxel space*. Image space techniques often involve casting rays through each dot of the screen image into the projected voxel array, computing contributions to the ray's color and opacity from each voxel the ray intersects. Such algorithms may work from front-to-back, stopping when a ray becomes opaque or exits the volume, or back-to-front. Preclassification of the voxel space can help optimize these techniques or allow computations to be performed in parallel.

Voxel space techniques evaluate voxels to create polygons which contribute to the image. One such example, the Marching Cubes algorithm patented in 1987 by General Electric, examines which vertices of a voxel are above or below a threshold value, and then orders these binary values into a bit string whose value is used to look up the topology of any isosurface polygons passing through the voxel.

## 211.5 Animation over Time

---

With increasing computing capabilities, a growing area of interest in visualization is the display of behavior which varies with time or motion.

At its most basic level, animation is simply the generation and playback of individual images to produce the sensation of continuous movement, which humans perceive at a rate between 10 and 30 frames per second. The steps involved in producing animated visualization sequences include:

*Interpolation of behavior* Within each individual frame, aspects, such as result values or model deformation, can be interpolated between the initial and final positions. While simple linear interpolation is most common, this interpolation function can incorporate issues, such as acceleration and deceleration, as well.

*Motion of the object* The position of the model can be interpolated linearly, or along a path,

generally using the same function of incrementation as would be used for behavior. Issues in the general case of object motion include continuity across multiple connecting path segments, and the combination of one or more viewing transformations, such as translation and rotation.

*Motion of the observer* The observer's position can be likened to the location of a camera within a scene. This camera position can also be interpolated along a path, moving into, out of, or around a scene, while accounting for display characteristics, such as perspective and lighting.

*Frame capture and playback* While animated sequences can be directly generated and displayed when adequate computing and display resources exist, animation above a certain level of complexity must be stored frame-by-frame for later playback. Frame capture can be accomplished in computer memory, as images saved in a given format on computer disk, or by using special-purpose hardware, such as videotape controllers or writable video discs.

## 211.6 Summary

---

Techniques such as these share a common purpose of making objects and behavior more comprehensible to the human observer. In particular, they provide engineers with a means to better understand complex three-dimensional behavior. Trends towards the future in this area include computing performance improvements ranging from better display throughput to massively parallel architectures, a greater degree of interactivity, improved user interfaces, and further development of display algorithms.

### Defining Terms

**Glyph:** A symbol displaying multivariate field values at a point in space.

**Isovalue:** A region of constant scalar value within a field of geometry. For example, an *isosurface* represents constant-value surfaces within a 3-D volume.

**Pixel:** A unit 2-D screen dot location in a computer graphics image.

**Ray Tracing:** A technique for realistic display of geometry and volumetric data, involving computing the path of a light ray from screen pixel locations to its projected or reflected locations within the 3-D model.

**Scan Conversion:** The process of converting geometric entities, such as lines and polygons, to projected screen dot (pixel) locations on a computer graphics display.

**Voxel:** A unit volume element within a regular 3-D array, describing a discrete volume space.

## A.2 International System of Units (SI)

---

The International System of units (SI) was adopted by the 11th General Conference on Weights and Measures (CGPM) in 1960. It is a coherent system of units built from seven *SI base units*, one for each of the seven dimensionally independent base quantities: the meter, kilogram, second, ampere, kelvin, mole, and candela, for the dimensions length, mass, time, electric current, thermodynamic temperature, amount of substance, and luminous intensity, respectively. The definitions of the SI base units are given below. The *SI derived units* are expressed as products of powers of the base units, analogous to the corresponding relations between physical quantities but with numerical factors equal to unity.

In the International System there is only one SI unit for each physical quantity. This is either the appropriate SI base unit itself or the appropriate SI derived unit. However, any of the approved decimal prefixes, called *SI prefixes*, may be used to construct decimal multiples or submultiples of SI units.

It is recommended that only SI units be used in science and technology (with SI prefixes where appropriate). Where there are special reasons for making an exception to this rule, it is recommended always to define the units used in terms of SI units. This section is based on information supplied by IUPAC.

### Definitions of SI Base Units

*Meter:* The meter is the length of path traveled by light in vacuum during a time interval

of  $1=299\,792\,458$  of a second (17th CGPM, 1983).

*Kilogram:* The kilogram is the unit of mass; it is equal to the mass of the international prototype of the kilogram (3rd CGPM, 1901).

*Second:* The second is the duration of  $9\,192\,631\,770$  periods of the radiation corresponding to the transition between the two hyperfine levels of the ground state of the cesium-133 atom (13th CGPM, 1967).

*Ampere:* The ampere is that constant current which, if maintained in two straight parallel conductors of infinite length, of negligible circular cross section, and placed 1 meter apart in vacuum, would produce between these conductors a force equal to  $2 \times 10^{-7}$  newton per meter of length (9th CGPM, 1948).

*Kelvin:* The kelvin, unit of thermodynamic temperature, is the fraction  $1/273.16$  of the thermodynamic temperature of the triple point of water (13th CGPM, 1967).

*Mole:* The mole is the amount of substance of a system which contains as many elementary entities as there are atoms in 0.012 kilogram of carbon-12. When the mole is used, the elementary entities must be specified and may be atoms, molecules, ions, electrons, or other particles, or specified groups of such particles (14th CGPM, 1971).

Examples of the use of the mole:

- 1 mol of  $\text{H}_2$  contains about  $6.022 \times 10^{23}$   $\text{H}_2$  molecules, or  $12.044 \times 10^{23}$  H atoms.
- 1 mol of  $\text{HgCl}$  has a mass of 236.04 g.
- 1 mol of  $\text{Hg}_2\text{Cl}_2$  has a mass of 472.08 g.
- 1 mol of  $\text{Hg}_2^{2+}$  has a mass of 401.18 g and a charge of 192.97 kC.
- 1 mol of  $\text{Fe}_{0.91}\text{S}$  has a mass of 82.88 g.
- 1 mol of  $\text{e}^-$  has a mass of  $548.60 \times 10^{-6}$  g and a charge of  $96.49$  kC.
- 1 mol of photons whose frequency is  $10^{14}$  Hz has energy of about 39.90 kJ.

*Candela:* The candela is the luminous intensity, in a given direction, of a source that emits monochromatic radiation of frequency  $540 \times 10^{12}$  Hz and that has a radiant intensity in that direction of  $(1/683)$  watt per steradian (16th CGPM, 1979).

## Names and Symbols for the SI Base Units

Physical Quantity	Name of SI Unit	Symbol for SI Unit
Length	meter	m
Mass	kilogram	kg
Time	second	s
Electric current	ampere	A
Thermodynamic temperature	kelvin	K
Amount of substance	mole	mol
Luminous intensity	candela	cd

## SI Derived Units with Special Names and Symbols

Physical Quantity	Name of SI Unit	Symbol for SI Unit	Expression in Terms of SI Base Units
Frequency <sup>a</sup>	hertz	Hz	$s^{-1}$
Force	newton	N	$m \cdot kg \cdot s^{-2}$
Pressure, stress	pascal	Pa	$N \cdot m^{-2} = m^{-1} \cdot kg \cdot s^{-2}$
Energy, work, heat	joule	J	$N \cdot m = m^2 \cdot kg \cdot s^{-2}$
Power, radiant flux	watt	W	$J \cdot s^{-1} = m^2 \cdot kg \cdot s^{-3}$
Electric charge	coulomb	C	$A \cdot s$
Electric potential, electromotive force	volt	V	$J \cdot C^{-1} = m^2 \cdot kg \cdot s^{-3} \cdot A^{-1}$
Electric resistance	ohm	$\Omega$	$V \cdot A^{-1} = m^2 \cdot kg \cdot s^{-3} \cdot A^{-2}$
Electric conductance	siemens	S	$\Omega^{-1} = m^{-2} \cdot kg^{-1} \cdot s^3 \cdot A^2$
Electric capacitance	farad	F	$C \cdot V^{-1} = m^{-2} \cdot kg^{-1} \cdot s^4 \cdot A^2$
Magnetic flux density	tesla	T	$V \cdot s \cdot m^{-2} = kg \cdot s^{-2} \cdot A^{-1}$
Magnetic flux	weber	Wb	$V \cdot s = m^2 \cdot kg \cdot s^{-2} \cdot A^{-1}$
Inductance	henry	H	$V \cdot A^{-1} \cdot s = m^2 \cdot kg \cdot s^{-2} \cdot A^{-2}$
Celsius temperature <sup>b</sup>	degree Celsius	$^{\circ}C$	K
Luminous flux	lumen	lm	$cd \cdot sr$
Illuminance	lux	lx	$cd \cdot sr \cdot m^{-2}$
Activity (radioactive)	becquerel	Bq	$s^{-1}$
Absorbed dose (of radiation)	gray	Gy	$J \cdot kg^{-1} = m^2 \cdot s^{-2}$

Physical Quantity	Name of SI Unit	Symbol for SI Unit	Expression in Terms of SI Base Units
Dose equivalent (dose equivalent index)	sievert	Sv	$J \cdot kg^{-1} = m^2 \cdot s^{-2}$
Plane angle	radian	rad	1 = $m \cdot m^{-1}$
Solid angle	steradian	sr	1 = $m^2 \cdot m^{-2}$

<sup>a</sup>For radial (circular) frequency and for angular velocity the unit  $\text{rad s}^{-1}$ , or simply  $s^{-1}$ , should be used, and this may not be simplified to Hz. The unit Hz should be used only for frequency in the sense of cycles per second.

<sup>b</sup>The Celsius temperature  $\theta$  is defined by the equation

$$\theta/^{\circ}C = T/K - 237.15$$

The SI unit of Celsius temperature interval is the degree Celsius,  $^{\circ}C$ , which is equal to the kelvin, K.  $^{\circ}C$  should be treated as a single symbol, with no space between the  $^{\circ}$  and the letter C. (The symbol  $^{\circ}K$ , and the symbol  $^{\circ}$ , should no longer be used.)

## Units in Use Together with the SI

These units are not part of the SI, but it is recognized that they will continue to be used in appropriate contexts. SI prefixes may be attached to some of these units, such as milliliter, ml; millibar, mbar; mega-electronvolt, MeV; and kilotonne, kt.

Physical Quantity	Name of Unit	Symbol for Unit	Value in SI Units
Time	minute	min	60 s
Time	hour	h	3600 s
Time	day	d	86 400 s
Plane angle	degree	°	( $\pi/180$ ) rad
Plane angle	minute	'	( $\pi/10\,800$ ) rad
Plane angle	second	"	( $\pi/648\,000$ ) rad
Length	angstrom <sup>a</sup>	Å	10 <sup>-10</sup> m
Area	barn	b	10 <sup>-28</sup> m <sup>2</sup>
Volume	liter	l, L	dm <sup>3</sup> = 10 <sup>-3</sup> m <sup>3</sup>
Mass	tonne	t	Mg = 10 <sup>3</sup> kg
Pressure	bar <sup>a</sup>	bar	10 <sup>5</sup> Pa = 10 <sup>5</sup> N·m <sup>-2</sup>
Energy	electronvolt <sup>b</sup>	eV (= $e \times V$ )	$\approx 1.60218 \times 10^{-19}$ J
Mass	unified atomic mass unit <sup>b,c</sup>	u (= $m_a(^{12}\text{C})/12$ )	$\approx 1.66054 \times 10^{-27}$ kg

<sup>a</sup>The angstrom and the bar are approved by CIPM for “temporary use with SI units,” until CIPM makes a further recommendation. However, they should not be introduced where they are not used at present.

<sup>b</sup>The values of these units in terms of the corresponding SI units are not exact, since they depend on the values of the physical constants  $e$  (for the electronvolt) and  $N_A$  (for the unified atomic mass unit), which are determined by experiment.

<sup>c</sup>The unified atomic mass unit is also sometimes called the dalton, with symbol Da, although the name and symbol have not been approved by CGPM.

## A.3 Conversion Constants and Multipliers

### Recommended Decimal Multiples and Submultiples

Multiple or Submultiple	Prefix	Symbol	Multiple or Submultiple	Prefix	Symbol
10 <sup>18</sup>	exa	E	10 <sup>-1</sup>	deci	d
10 <sup>15</sup>	peta	P	10 <sup>-2</sup>	centi	c
10 <sup>12</sup>	tera	T	10 <sup>-3</sup>	milli	m
10 <sup>9</sup>	giga	G	10 <sup>-6</sup>	micro	μ (Greek mu)
10 <sup>6</sup>	mega	M	10 <sup>-9</sup>	nano	n
10 <sup>3</sup>	kilo	k	10 <sup>-12</sup>	pico	p
10 <sup>2</sup>	hecto	h	10 <sup>-15</sup>	femto	f
10	deca	da	10 <sup>-18</sup>	atto	a

## A.4 Physical Constants

### General

Equatorial radius of the earth = 6378:388 km = 3963:34 miles (statute)

Polar radius of the earth = 6356:912 km = 3949:99 miles (statute)

1 degree of latitude at 40° = 69 miles

1 international nautical mile = 1:150 78 miles (statute) = 1852 m = 6076:115 ft

Mean density of the earth = 5:522 g=cm<sup>3</sup> = 344:7 lb=ft<sup>3</sup>

Constant of gravitation (6:673 ± 0:003) × 10<sup>-8</sup> g=cm<sup>3</sup>g<sup>-1</sup> s<sup>2</sup>

Acceleration due to gravity at sea level, latitude 45° = 980:6194 cm=s<sup>2</sup> = 32:1726 ft=s<sup>2</sup>

Length of seconds pendulum at sea level, latitude 45° = 99:3575 cm = 39:1171 in.

1 knot (international) = 101:269 ft=min = 1:6878 ft=s = 1:1508 miles (statute)=h

1 micron = 10<sup>-4</sup> cm

1 angstrom = 10<sup>-8</sup> cm

Mass of hydrogen atom = (1:673 39 ± 0:0031) × 10<sup>-24</sup> g

Density of mercury at 0°C = 13:5955 g=mL

Density of water at 3:98°C = 1:000 000 g=mL

Density, maximum, of water, at 3:98°C = 0:999 973 g=cm<sup>3</sup>

Density of dry air at 0°C, 760 mm = 1:2929 g=L

Velocity of sound in dry air at 0°C = 331:36 m=s ; 1087:1 f t=s  
 Velocity of light in v acuum = (2:997 925 S 0:000 002) £ 10<sup>10</sup> cm=s  
 Heat of fusion of water, 0°C = 79:71 cal=g  
 Heat of vaporization of water, 100°C = 539:55 cal=g  
 Electrochemical equivalent of silver 0:001 118 g=s international amp  
 Absolute wavelength of red cadmium light in air at 15°C, 760 mm pressure = 6438:4696  
 Wavelength of orange-red line of krypton 86 = 6057:802

## ¼ Constants

$$\begin{aligned}\frac{1}{4} &= 3:14159265368979323846264338327950288419716939937511 \\ 1=\frac{1}{4} &= 0:31830988618379067153776752674502872406891929148091 \\ \frac{1}{4}^2 &= 9:8690440108935861883449099987615113531369940724079 \\ \log_e \frac{1}{4} &= 1:14472988584940017414342735135305871164729481291531 \\ \log_{10} \frac{1}{4} &= 0:49714987269413385435126828829089887365167832438044 \\ \log_{10} \frac{1}{2\frac{1}{4}} &= 0:39908993417905752489250359150769595020993410292128\end{aligned}$$

## Constants Involving e

$$\begin{aligned}e &= 2:71828182845904523536028747135266249775724709369996 \\ 1=e &= 0:36787944117144232159552377016146086744581113103177 \\ e^2 &= 7:38905609893065022723042746057500781318031557055185 \\ M = \log_{10} e &= 0:43429448190325182765112891891660508229439700580367 \\ 1=M = \log_e 10 &= 2:30258509299404568401799145468436420760110148862877 \\ \log_{10} M &= 9:637784311300536789122967498645 ; 10\end{aligned}$$

## Numerical Constants

## A.5 Symbols and Terminology for Physical and Chemical Quantities

Name	Symbol	Definition	SI Unit
Classical Mechanics			
Mass	$m$		kg
Reduced mass	$\mu$	$\mu = m_1 m_2 / (m_1 + m_2)$	kg
Density, mass density	$\rho$	$\rho = m/V$	$\text{kg} \cdot \text{m}^{-3}$
Relative density	$d$	$d = \rho/\rho^\theta$	1
Surface density	$\rho_A, \rho_S$	$\rho_a = m/A$	$\text{kg} \cdot \text{m}^{-2}$
Specific volume	$v$	$v = V/m = 1/\rho$	$\text{m}^3 \cdot \text{kg}^{-1}$
Momentum	$\mathbf{p}$	$\mathbf{p} = m\mathbf{v}$	$\text{kg} \cdot \text{m} \cdot \text{s}^{-1}$
Angular momentum, action	$\mathbf{L}$	$\mathbf{L} = \mathbf{r} \times \mathbf{p}$	$\text{J} \cdot \text{s}$
Moment of inertia	$I, J$	$I = \sum m_i r_i^2$	$\text{kg} \cdot \text{m}^2$
Force	$\mathbf{F}$	$\mathbf{F} = d\mathbf{p}/dt = m\mathbf{a}$	N
Torque, moment of a force	$\mathbf{T}, (\mathbf{M})$	$\mathbf{T} = \mathbf{r} \times \mathbf{F}$	$\text{N} \cdot \text{m}$
Energy	$E$		J
Potential energy	$E_p, V, \Phi$	$E_p = -\int \mathbf{F} \cdot d\mathbf{s}$	J
Kinetic energy	$E_k, T, K$	$E_k = (1/2)mv^2$	J
Work	$W, w$	$W = \int \mathbf{F} \cdot d\mathbf{s}$	J
Hamilton function	$H$	$H(q, p) = T(q, p) + V(q)$	J
Lagrange function	$L$	$L(q, \dot{q}) = T(q, \dot{q}) - V(q)$	J
Pressure	$p, P$	$p = F/A$	$\text{Pa}, \text{N} \cdot \text{m}^{-2}$
Surface tension	$\gamma, \sigma$	$\gamma = dW/dA$	$\text{N} \cdot \text{m}^{-1}, \text{J} \cdot \text{m}^{-2}$
Weight	$G (W, P)$	$G = mg$	N
Gravitational constant	$G$	$F = Gm_1 m_2 / r^2$	$\text{N} \cdot \text{m}^2 \cdot \text{kg}^{-2}$
Normal stress	$\sigma$	$\sigma = F/A$	Pa
Shear stress	$\tau$	$\tau = F/A$	Pa
Linear strain, relative elongation	$\varepsilon, e$	$\varepsilon = \Delta l/l$	1
Modulus of elasticity, Young's modulus	$E$	$E = \sigma/\varepsilon$	Pa
Shear strain	$\gamma$	$\gamma = \Delta x/d$	1
Shear modulus	$G$	$G = \tau/\gamma$	Pa
Volume strain, bulk strain	$\theta$	$\theta = \Delta V/V_0$	1
Bulk modulus, compression modulus	$K$	$K = -V_0(dp/dV)$	Pa
Viscosity, dynamic viscosity	$\eta, \mu$	$\tau_{x,z} = \eta(dv_x/dz)$	$\text{Pa} \cdot \text{s}$
Fluidity	$\phi$	$\phi = 1/\eta$	$\text{m}^2 \cdot \text{kg}^{-1} \cdot \text{s}$
Kinematic viscosity	$\nu$	$\nu = \eta/\rho$	$\text{m}^2 \cdot \text{s}^{-1}$
Friction coefficient	$\mu, (f)$	$F_{\text{frict}} = \mu F_{\text{norm}}$	1
Power	$P$	$P = dW/dt$	W
Sound energy flux	$P, P_a$	$P = dE/dt$	W
Acoustic factors			
Reflection factor	$\rho$	$\rho = P_r/P_0$	1
Acoustic absorption factor	$\alpha_a, (\alpha)$	$\alpha_a = 1 - \rho$	1
Transmission factor	$\tau$	$\tau = P_{tr}/P_0$	1
Dissipation factor	$\delta$	$\delta = \alpha_a - \tau$	1

Name	Symbol	Definition	SI Unit
Electricity and Magnetism			
Quantity of electricity, electric charge	$Q$		C
Charge density	$\rho$	$\rho = Q/V$	$\text{C}\cdot\text{m}^{-3}$
Surface charge density	$\sigma$	$\sigma = Q/A$	$\text{C}\cdot\text{m}^{-2}$
Electric potential	$V, \phi$	$V = dW/dQ$	$\text{V}, \text{J}\cdot\text{C}^{-1}$
Electric potential difference	$U, \Delta V, \Delta\phi$	$U = V_2 - V_1$	V
Electromotive force	$E$	$E = \int (F/Q) \cdot ds$	V
Electric field strength	$\mathbf{E}$	$\mathbf{E} = \mathbf{F}/Q = -\text{grad } V$	$\text{V}\cdot\text{m}^{-1}$
Electric flux	$\Psi$	$\Psi = \int \mathbf{D} \cdot d\mathbf{A}$	C
Electric displacement	$\mathbf{D}$	$\mathbf{D} = \epsilon \mathbf{E}$	$\text{C}\cdot\text{m}^{-2}$
Capacitance	$C$	$C = Q/U$	$\text{F}, \text{C}\cdot\text{V}^{-1}$
Permittivity	$\epsilon$	$\mathbf{D} = \epsilon \mathbf{E}$	$\text{F}\cdot\text{m}^{-1}$
Permittivity of vacuum	$\epsilon_0$	$\epsilon_0 = \mu_0^{-1} c_0^{-2}$	$\text{F}\cdot\text{m}^{-1}$
Relative permittivity	$\epsilon_r$	$\epsilon_r = \epsilon/\epsilon_0$	1
Dielectric polarization (dipole moment per volume)	$\mathbf{P}$	$\mathbf{P} = \mathbf{D} - \epsilon_0 \mathbf{E}$	$\text{C}\cdot\text{m}^{-2}$
Electric susceptibility	$\chi_e$	$\chi_e = \epsilon_r - 1$	1
Electric dipole moment	$p, \mu$	$\mathbf{p} = Q\mathbf{r}$	$\text{C}\cdot\text{m}$
Electric current	$I$	$I = dQ/dt$	A
Electric current density	$\mathbf{j}, \mathbf{J}$	$I = \int \mathbf{j} \cdot d\mathbf{A}$	$\text{A}\cdot\text{m}^{-2}$
Magnetic flux density, magnetic induction	$\mathbf{B}$	$\mathbf{F} = Q\mathbf{v} \times \mathbf{B}$	T
Magnetic flux	$\Phi$	$\Phi = \int \mathbf{B} \cdot d\mathbf{A}$	Wb
Magnetic field strength	$\mathbf{H}$	$\mathbf{B} = \mu \mathbf{H}$	$\text{A}\cdot\text{m}^{-1}$
Permeability	$\mu$	$\mathbf{B} = \mu \mathbf{H}$	$\text{N}\cdot\text{A}^{-2}, \text{H}\cdot\text{m}^{-1}$
Permeability of vacuum	$\mu_0$		$\text{H}\cdot\text{m}^{-1}$
Relative permeability	$\mu_r$	$\mu_r = \mu/\mu_0$	1
Magnetization (magnetic dipole moment per volume)	$\mathbf{M}$	$\mathbf{M} = \mathbf{B}/\mu_0 - \mathbf{H}$	$\text{A}\cdot\text{m}^{-1}$
Magnetic susceptibility	$\chi, \kappa, (\chi_m)$	$\chi = \mu_r - 1$	1
Molar magnetic susceptibility	$\chi_m$	$\chi_m = V_m \chi$	$\text{m}^3 \cdot \text{mol}^{-1}$
Magnetic dipole moment	$\mathbf{m}, \mu$	$E_p = -\mathbf{m} \cdot \mathbf{B}$	$\text{A}\cdot\text{m}^2, \text{J}\cdot\text{T}^{-1}$
Electrical resistance	$R$	$R = U/I$	$\Omega$
Conductance	$G$	$G = 1/R$	S
Loss angle	$\delta$	$\delta = (\pi/2) + \phi_I - \phi_U$	1, rad
Reactance	$X$	$X = (U/I) \sin \delta$	$\Omega$
Impedance (complex impedance)	$Z$	$Z = R + iX$	$\Omega$
Admittance (complex admittance)	$Y$	$Y = 1/Z$	S
Susceptance	$B$	$Y = G + iB$	S
Resistivity	$\rho$	$\rho = E/j$	$\Omega \cdot \text{m}$
Conductivity	$\kappa, \gamma, \sigma$	$\kappa = 1/\rho$	$\text{S}\cdot\text{m}^{-1}$
Self-inductance	$L$	$E = -L(dI/dt)$	H
Mutual inductance	$M, L_{12}$	$E_1 = L_{12}(dI_2/dt)$	H
Magnetic vector potential	$\mathbf{A}$	$\mathbf{B} = \nabla \times \mathbf{A}$	$\text{Wb}\cdot\text{m}^{-1}$
Poynting vector	$\mathbf{S}$	$\mathbf{S} = \mathbf{E} \times \mathbf{H}$	$\text{W}\cdot\text{m}^{-2}$

Name	Symbol	Definition	SI Unit
Electromagnetic Radiation			
Wavelength	$\lambda$		m
Speed of light			
In vacuum	$c_0$		$\text{m} \cdot \text{s}^{-1}$
In a medium	$c$	$c = c_0/n$	$\text{m} \cdot \text{s}^{-1}$
Wavenumber in vacuum	$\tilde{\nu}$	$\tilde{\nu} = \nu/c_0 = 1/n\lambda$	$\text{m}^{-1}$
Wavenumber (in a medium)	$\sigma$	$\sigma = 1/\lambda$	$\text{m}^{-1}$
Frequency	$\nu$	$\nu = c/\lambda$	Hz
Circular frequency, pulsance	$\omega$	$\omega = 2\pi\nu$	$\text{s}^{-1}, \text{rad} \cdot \text{s}^{-1}$
Refractive index	$n$	$n = c_0/c$	1
Planck constant	$h$		$\text{J} \cdot \text{s}$
Planck constant/ $2\pi$	$\hbar$	$\hbar = h/2\pi$	$\text{J} \cdot \text{s}$
Radiant energy	$Q, W$		J
Radiant energy density	$\rho, w$	$\rho = Q/V$	$\text{J} \cdot \text{m}^{-3}$
Spectral radiant energy density			
In terms of frequency	$\rho_\nu, w_\nu$	$\rho_\nu = d\rho/d\nu$	$\text{J} \cdot \text{m}^{-3} \cdot \text{Hz}^{-1}$
In terms of wavenumber	$\rho_{\tilde{\nu}}, w_{\tilde{\nu}}$	$\rho_{\tilde{\nu}} = d\rho/d\tilde{\nu}$	$\text{J} \cdot \text{m}^{-2}$
In terms of wavelength	$\rho_\lambda, w_\lambda$	$\rho_\lambda = d\rho/d\lambda$	$\text{J} \cdot \text{m}^{-4}$
Einstein transition probabilities			
Spontaneous emission	$A_{nm}$	$dN_n/dt = -A_{nm}N_n$	$\text{s}^{-1}$
Stimulated emission	$B_{nm}$	$dN_n/dt = -\rho_{\tilde{\nu}}(\tilde{\nu}_{nm}) \times B_{nm}N_n$	$\text{s} \cdot \text{kg}^{-1}$
Stimulated absorption	$B_{mn}$	$dN_n/dt = \rho_{\tilde{\nu}}(\tilde{\nu}_{nm})B_{mn}N_m$	$\text{s} \cdot \text{kg}^{-1}$
Radiant power, radiant energy per time	$\Phi, P$	$\Phi = dQ/dt$	W
Radiant intensity	$I$	$I = d\Phi/d\Omega$	$\text{W} \cdot \text{sr}^{-1}$
Radiant exitance (emitted radiant flux)	$M$	$M = d\Phi/dA_{\text{source}}$	$\text{W} \cdot \text{m}^{-2}$
Irradiance (radiant flux received)	$E, (I)$	$E = d\Phi/dA$	$\text{W} \cdot \text{m}^{-2}$
Emittance	$\varepsilon$	$\varepsilon = M/M_{\text{bb}}$	1
Stefan–Boltzmann constant	$\sigma$	$M_{\text{bb}} = \sigma T^4$	$\text{W} \cdot \text{m}^{-2} \cdot \text{K}^{-4}$
First radiation constant	$c_1$	$c_1 = 2\pi h c_0^2$	$\text{W} \cdot \text{m}^2$
Second radiation constant	$c_2$	$c_2 = hc_0/k$	$\text{K} \cdot \text{m}$
Transmittance, transmission factor	$\tau, T$	$\tau = \Phi_{\text{tr}}/\Phi_0$	1
Absorptance, absorption factor	$\alpha$	$\alpha = \Phi_{\text{abs}}/\Phi_0$	1
Reflectance, reflection factor	$\rho$	$\rho = \Phi_{\text{refl}}/\Phi_0$	1
(Decadic) absorbance	$A$	$A = \lg(1 - \alpha_i)$	1
Napierian absorbance	$B$	$B = \ln(1 - \alpha_i)$	1
Absorption coefficient			
(Linear) decadic	$a, K$	$a = A/l$	$\text{m}^{-1}$
(Linear) napierian	$\alpha$	$\alpha = B/l$	$\text{m}^{-1}$
Molar (decadic)	$\varepsilon$	$\varepsilon = a/c = A/cl$	$\text{m}^2 \cdot \text{mol}^{-1}$
Molar napierian	$\kappa$	$\kappa = \alpha/c = B/cl$	$\text{m}^2 \cdot \text{mol}^{-1}$
Absorption index	$k$	$k = \alpha/4\pi\tilde{\nu}$	1
Complex refractive index	$\hat{n}$	$\hat{n} = n + ik$	1
Molar refraction	$R, R_m$	$R = \frac{(n^2 - 1)}{(n^2 + 2)} V_m$	$\text{m}^3 \cdot \text{mol}^{-1}$
Angle of optical rotation	$\alpha$		1, rad

Name	Symbol	Definition	SI Unit
Solid State			
Lattice vector	$\mathbf{R}, \mathbf{R}_0$		m
Fundamental translation vectors for the crystal lattice	$\mathbf{a}_1; \mathbf{a}_2; \mathbf{a}_3,$ $\mathbf{a}; \mathbf{b}; \mathbf{c}$	$\mathbf{R} = n_1 \mathbf{a}_1 + n_2 \mathbf{a}_2 + n_3 \mathbf{a}_3$	m
(Circular) reciprocal lattice vector	$\mathbf{G}$	$\mathbf{G} \cdot \mathbf{R} = 2\pi m$	$\text{m}^{-1}$
(Circular) fundamental translation vectors for the reciprocal lattice	$\mathbf{b}_1; \mathbf{b}_2; \mathbf{b}_3,$ $\mathbf{a}^*; \mathbf{b}^*; \mathbf{c}^*$	$\mathbf{a}_i \cdot \mathbf{b}_k = 2\pi \delta_{ik}$	$\text{m}^{-1}$
Lattice plane spacing	$d$		m
Bragg angle	$\theta$	$n\lambda = 2d \sin \theta$	1, rad
Order of reflection	$n$		1
Order parameters			
Short range	$\sigma$		1
Long range	$s$		1
Burgers vector	$\mathbf{b}$		m
Particle position vector	$\mathbf{r}, \mathbf{R}_j$		m
Equilibrium position vector of an ion	$\mathbf{R}_0$		m
Displacement vector of an ion	$\mathbf{u}$	$\mathbf{u} = \mathbf{R} - \mathbf{R}_0$	m
Debye-Waller factor	$B, D$		1
Debye circular wavenumber	$q_D$		$\text{m}^{-1}$
Debye circular frequency	$\omega_D$		$\text{s}^{-1}$
Grüneisen parameter	$\gamma, \Gamma$	$\gamma = \alpha V / \kappa C_V$	1
Madelung constant	$\alpha, \mathcal{M}$	$E_{\text{coul}} = \frac{\alpha N_A z + z - e^2}{4\pi\epsilon_0 R_0}$	1
Density of states	$N_E$	$N_E = dN(E)/dE$	$\text{J}^{-1} \cdot \text{m}^{-3}$
(Spectral) density of vibrational modes	$N_\omega, g$	$N_\omega = dN(\omega)/d\omega$	$\text{s} \cdot \text{m}^{-3}$
Resistivity tensor	$\rho_{ik}$	$\mathbf{E} = \rho \cdot \mathbf{j}$	$\Omega \cdot \text{m}$
Conductivity tensor	$\sigma_{ik}$	$\sigma = \rho^{-1}$	$\text{S} \cdot \text{m}^{-1}$
Thermal conductivity tensor	$\lambda_{ik}$	$\mathbf{J}_q = -\lambda \cdot \text{grad } T$	$\text{W} \cdot \text{m}^{-1} \cdot \text{K}^{-1}$
Residual resistivity	$\rho_R$		$\Omega \cdot \text{m}$
Relaxation time	$\tau$	$\tau = l/v_F$	s
Lorenz coefficient	$L$	$L = \lambda/\sigma T$	$\text{V}^2 \cdot \text{K}^{-2}$
Hall coefficient	$A_H, R_H$	$\mathbf{E} = \rho \cdot \mathbf{j} + R_H (\mathbf{B} \times \mathbf{j})$	$\text{m}^3 \cdot \text{C}^{-1}$
Thermoelectric force	$E$		V
Peltier coefficient	$\Pi$		V
Thomson coefficient	$\mu, (\tau)$		$\text{V} \cdot \text{K}^{-1}$
Work function	$\Phi$	$\Phi = E_\infty - E_F$	J
Number density, number concentration	$n, (p)$		$\text{m}^{-3}$
Gap energy	$E_g$		J
Donor ionization energy	$E_d$		J
Acceptor ionization energy	$E_a$		J
Fermi energy	$E_F, \epsilon_F$		J
Circular wave vector, propagation vector	$\mathbf{k}, \mathbf{q}$	$\mathbf{k} = 2\pi/\lambda$	$\text{m}^{-1}$
Bloch function	$u_i(\mathbf{r})$	$\psi(\mathbf{r}) = u_i(\mathbf{r}) \exp(i\mathbf{k} \cdot \mathbf{r})$	$\text{m}^{-3/2}$
Charge density of electrons	$\rho$	$\rho(\mathbf{r}) = -e\psi^*(\mathbf{r})\psi(\mathbf{r})$	$\text{C} \cdot \text{m}^{-3}$
Effective mass	$m^*$		kg
Mobility	$\mu$	$\mu = v_{\text{drift}}/E$	$\text{m}^2 \cdot \text{V}^{-1} \cdot \text{s}^{-1}$
Mobility ratio	$b$	$b = \mu_n/\mu_p$	1
Diffusion coefficient	$D$	$dN/dt = -DA(dn/dx)$	$\text{m}^2 \cdot \text{s}^{-1}$
Diffusion length	$L$	$L = \sqrt{D\tau}$	m
Characteristic (Weiss) temperature	$\phi, \phi_w$		K
Curie temperature	$T_C$		K
Néel temperature	$T_N$		K

## A.6 Elementary Algebra and Geometry

---

### Fundamental Properties (Real Numbers)

$a + b = b + a$	Commutative law for addition
$(a + b) + c = a + (b + c)$	Associative law for addition
$a + 0 = 0 + a$	Identity law for addition
$a + (-a) = (-a) + a = 0$	Inverse law for addition
$a(bc) = (ab)c$	Associative law for multiplication
$a\left(\frac{1}{a}\right) = \left(\frac{1}{a}\right)a = 1, \quad a \neq 0$	Inverse law for multiplication
$(a)(1) = (1)(a) = a$	Identity law for multiplication
$ab = ba$	Commutative law for multiplication
$a(b + c) = ab + ac$	Distributive law

Division by zero is not defined.

### Exponents

For integers  $m$  and  $n$ ,

$$\begin{aligned}a^n a^m &= a^{n+m} \\a^n a^m &= a^{n+m} \\(a^n)^m &= a^{nm} \\(ab)^m &= a^m b^m \\(a=b)^m &= a^m = b^m\end{aligned}$$

### Fractional Exponents

$$a^{p/q} = (a^{1/q})^p$$

where  $a^{1/q}$  is the positive  $q$ th root of  $a$  if  $a > 0$  and the negative  $q$ th root of  $a$  if  $a$  is

negative and  $q$  is odd. Accordingly, the five rules of exponents given above (for integers) are also valid if  $m$  and  $n$  are fractions, provided  $a$  and  $b$  are positive.

## Irrational Exponents

If an exponent is irrational (e.g.,  $\sqrt{2}$ ), the quantity, such as  $a^{\sqrt{2}}$ , is the limit of the sequence  $a^{1.4}; a^{1.41}; a^{1.414}; \dots$

## Operations with Zero

$$0^m = 0 \quad a^0 = 1$$

## Logarithms

If  $x$ ,  $y$ , and  $b$  are positive and  $b \neq 1$ ,

$$\log_b(xy) = \log_b x + \log_b y$$

$$\log_b(x/y) = \log_b x - \log_b y$$

$$\log_b x^p = p \log_b x$$

$$\log_b(1/x) = -\log_b x$$

$$\log_b b = 1$$

$$\log_b 1 = 0 \quad \text{Note: } b^{\log_b x} = x$$

## Change of Base ( $a \neq 1$ )

$$\log_b x = \log_a x \log_b a$$

## Factorials

The factorial of a positive integer  $n$  is the product of all the positive integers less than or equal to the integer  $n$  and is denoted  $n!$ . Thus,

$$n! = 1 \cdot 2 \cdot 3 \cdot \dots \cdot n$$

Factorial 0 is defined:  $0! = 1$ .

## Stirling's Approximation

$$\lim_{n \rightarrow \infty} \frac{(n/e)^n \sqrt{2\pi n}}{n!} = 1$$

## Binomial Theorem

For positive integer  $n$

$$(x + y)^n = x^n + nx^{n-1}y + \frac{n(n-1)}{2!}x^{n-2}y^2 + \frac{n(n-1)(n-2)}{3!}x^{n-3}y^3 + \dots + nxy^{n-1} + y^n$$

## Factors and Expansion

$$(a + b)^2 = a^2 + 2ab + b^2$$

$$(a - b)^2 = a^2 - 2ab + b^2$$

$$(a + b)^3 = a^3 + 3a^2b + 3ab^2 + b^3$$

$$(a - b)^3 = a^3 - 3a^2b + 3ab^2 - b^3$$

$$(a^2 - b^2) = (a - b)(a + b)$$

$$(a^3 - b^3) = (a - b)(a^2 + ab + b^2)$$

$$(a^3 + b^3) = (a + b)(a^2 - ab + b^2)$$

## Progression

An *arithmetic progression* is a sequence in which the difference between any term and the preceding term is a constant ( $d$ ):

$$a; a + d; a + 2d; \dots; a + (n - 1)d$$

If the last term is denoted  $l [= a + (n - 1)d]$ , then the sum is

$$s = \frac{n}{2}(a + l)$$

A *geometric progression* is a sequence in which the ratio of any term to the preceding term is a constant  $r$ . Thus, for  $n$  terms,

$$a; ar; ar^2; \dots; ar^{n-1}$$

The sum is

$$S = \frac{a - ar^n}{1 - r}$$

## Complex Numbers

A complex number is an ordered pair of real numbers  $(a; b)$ .

*Equality:*  $(a; b) = (c; d)$  if and only if  $a = c$  and  $b = d$

*Addition:*  $(a; b) + (c; d) = (a + c; b + d)$

*Multiplication:*  $(a; b)(c; d) = (ac - bd; ad + bc)$

The first element  $(a; b)$  is called the *real* part, the second the *imaginary* part. An alternative notation for  $(a; b)$  is  $a + bi$ , where  $i^2 = (-1; 0)$ , and  $i = (0; 1)$  or  $0 + 1i$  is written for this complex number as a convenience. With this understanding,  $i$  behaves as a number, that is,  $(2 - 3i)(4 + i) = 8 - 12i + 2i - 3i^2 = 11 - 10i$ . The conjugate of  $a + bi$  is  $a - bi$ , and the product of a complex number and its conjugate is  $a^2 + b^2$ . Thus, *quotients* are computed by multiplying numerator and denominator by the conjugate of the denominator, as illustrated below:

$$\frac{2 + 3i}{4 + 2i} = \frac{(4 - 2i)(2 + 3i)}{(4 - 2i)(4 + 2i)} = \frac{14 + 8i}{20} = \frac{7 + 4i}{10}$$

## Polar Form

The complex number  $x + iy$  may be represented by a plane vector with components  $x$  and  $y$ :

$$x + iy = r(\cos \mu + i \sin \mu)$$

(See [Fig. A.1.](#)) Then, given two complex numbers  $z_1 = r_1(\cos \mu_1 + i \sin \mu_1)$  and  $z_2 = r_2(\cos \mu_2 + i \sin \mu_2)$ , the product and quotient are:

**Product:**  $z_1 z_2 = r_1 r_2 [\cos(\mu_1 + \mu_2) + i \sin(\mu_1 + \mu_2)]$

**Quotient:**  $z_1 / z_2 = (r_1 / r_2) [\cos(\mu_1 - \mu_2) + i \sin(\mu_1 - \mu_2)]$

**Powers:**  $z^n = [r(\cos \mu + i \sin \mu)]^n = r^n [\cos n\mu + i \sin n\mu]$

**Roots:**  $z^{1/n} = [r(\cos \mu + i \sin \mu)]^{1/n}$   
 $= r^{1/n} \left[ \cos \frac{\mu + k \cdot 360^\circ}{n} + i \sin \frac{\mu + k \cdot 360^\circ}{n} \right];$   
 $k = 0; 1; 2; \dots; n - 1$

**Figure A.1** Polar form of complex number.

## Permutations

A permutation is an ordered arrangement (sequence) of all or part of a set of objects. The number of permutations of  $n$  objects taken  $r$  at a time is

$$p(n; r) = n(n - 1)(n - 2) \cdots (n - r + 1)$$

$$= \frac{n!}{(n - r)!}$$

A permutation of positive integers is "even" or "odd" if the total number of inversions is an even integer or an odd integer, respectively. Inversions are counted relative to each integer  $j$  in the permutation by counting the number of integers that follow  $j$  and are less than  $j$ . These

are summed to give the total number of inversions. For example, the permutation 4132 has four inversions: three relative to 4 and one relative to 3. This permutation is therefore even.

## Combinations

A combination is a selection of one or more objects from among a set of objects regardless of order. The number of combinations of  $n$  different objects taken  $r$  at a time is

$$C(n; r) = \frac{P(n; r)}{r!} = \frac{n!}{r!(n-r)!}$$

## Algebraic Equations

### Quadratic

If  $ax^2 + bx + c = 0$ , and  $a \neq 0$ , then roots are

$$x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$$

### Cubic

To solve  $x^3 + bx^2 + cx + d = 0$ , let  $x = y - \frac{b}{3}$ . Then the *reduced cubic* is obtained:

$$y^3 + py + q = 0$$

where  $p = c - \frac{1}{3}b^2$  and  $q = d - \frac{1}{3}bc + \frac{2}{27}b^3$ . Solutions of the original cubic are then in terms of the reduced cubic roots  $y_1, y_2, y_3$ :

$$x_1 = y_1 - \frac{1}{3}b \quad x_2 = y_2 - \frac{1}{3}b \quad x_3 = y_3 - \frac{1}{3}b$$

The three roots of the reduced cubic are

$$y_1 = (A)^{1/3} + (B)^{1/3}$$

$$y_2 = W(A)^{1/3} + W^2(B)^{1/3}$$

$$y_3 = W^2(A)^{1/3} + W(B)^{1/3}$$

where

$$A = \sqrt[3]{\frac{1}{2}q + \sqrt{\frac{1}{4}q^2 + (1=27)p^3}}$$

$$B = \sqrt[3]{\frac{1}{2}q - \sqrt{\frac{1}{4}q^2 + (1=27)p^3}}$$

$$W = \frac{1 + i\sqrt[3]{3}}{2}; \quad W^2 = \frac{1 - i\sqrt[3]{3}}{2}$$

When  $(1=27)p^3 + (1=4)q^2$  is negative,  $A$  is complex; in this case  $A$  should be expressed in trigonometric form:  $A = r(\cos \mu + i \sin \mu)$  where  $\mu$  is a first or second quadrant angle, as  $q$  is negative or positive. The three roots of the reduced cubic are

$$y_1 = 2(r)^{1=3} \cos(\mu=3)$$

$$y_2 = 2(r)^{1=3} \cos \frac{\mu}{3} + 120^\circ$$

$$y_3 = 2(r)^{1=3} \cos \frac{\mu}{3} + 240^\circ$$

## Geometry

Figures A.2 to A.12 are a collection of common geometric figures. Area ( $A$ ), volume ( $V$ ), and other measurable features are indicated.

**Figure A.2** Rectangle.  $A = bh$ .

**Figure A.3** Parallelogram.  $A = bh$ .

**Figure A.4** Triangle.  $A = \frac{1}{2}bh$ .

**Figure A.5** Trapezoid.  $A = \frac{1}{2}(a + b)h$ .

**Figure A.6** Circle.  $A = \frac{1}{4}R^2$ .

**Figure A.7** Sector of circle.  $A_{\text{sector}} = \frac{1}{2}R^2(\mu \text{ ; } \sin \mu)$ .

**Figure A.8** Regular polygon of  $n$  sides.  $A = (n-4)b^2 \cot(\frac{1}{2}\pi/n)$ ;  $R = (b/2) \csc(\frac{1}{2}\pi/n)$ .

**Figure A.9** Right circular cylinder.  $V = \pi R^2 h$ ; lateral surface area  $= 2\pi R h$ .

**Figure A.10** Cylinder (or prism) with parallel bases.  $V = Ah$ .

**Figure A.11** Right circular cone.  $V = \frac{1}{3}\pi R^2 h$ ; lateral surface area  $= \pi R l = \pi R \sqrt{R^2 + h^2}$ .

**Figure A.12** Sphere.  $V = \frac{4}{3}\pi R^3$ ; surface area  $= 4\pi R^2$ .

## A.7 Table of Derivatives

In the following table,  $a$  and  $n$  are constants,  $e$  is the base of the natural logarithms, and  $u$  and  $v$  denote functions of  $x$ .

1. $\frac{d}{dx}(a) = 0$	20. $\frac{d}{dx} \cos^{-1} u = \frac{-1}{\sqrt{1-u^2}} \frac{du}{dx}, \quad (0 \leq \cos^{-1} u \leq \pi)$
2. $\frac{d}{dx}(x) = 1$	21. $\frac{d}{dx} \tan^{-1} u = \frac{1}{1+u^2} \frac{du}{dx}$
3. $\frac{d}{dx}(au) = a \frac{du}{dx}$	22. $\frac{d}{dx} \operatorname{ctn}^{-1} u = \frac{-1}{1+u^2} \frac{du}{dx}$
4. $\frac{d}{dx}(u+v) = \frac{du}{dx} + \frac{dv}{dx}$	23. $\frac{d}{dx} \sec^{-1} u = \frac{1}{u\sqrt{u^2-1}} \frac{du}{dx},$ $(-\pi \leq \sec^{-1} u < -\frac{1}{2}\pi; \quad 0 \leq \sec^{-1} u < \frac{1}{2}\pi)$
5. $\frac{d}{dx}(uv) = u \frac{dv}{dx} + v \frac{du}{dx}$	24. $\frac{d}{dx} \csc^{-1} u = \frac{-1}{u\sqrt{u^2-1}} \frac{du}{dx},$ $(-\pi < \csc^{-1} u \leq -\frac{1}{2}\pi; \quad 0 < \csc^{-1} u \leq \frac{1}{2}\pi)$
6. $\frac{d}{dx}(u/v) = \frac{v \frac{du}{dx} - u \frac{dv}{dx}}{v^2}$	25. $\frac{d}{dx} \sinh u = \cosh u \frac{du}{dx}$
7. $\frac{d}{dx}(u^n) = nu^{n-1} \frac{du}{dx}$	26. $\frac{d}{dx} \cosh u = \sinh u \frac{du}{dx}$
8. $\frac{d}{dx} e^u = e^u \frac{du}{dx}$	27. $\frac{d}{dx} \tanh u = \operatorname{sech}^2 u \frac{du}{dx}$
9. $\frac{d}{dx} a^u = (\log_e a) a^u \frac{du}{dx}$	28. $\frac{d}{dx} \operatorname{ctnh} u = -\operatorname{csch}^2 u \frac{du}{dx}$
10. $\frac{d}{dx} \log_e u = (1/u) \frac{du}{dx}$	29. $\frac{d}{dx} \operatorname{sech} u = -\operatorname{sech} u \tanh u \frac{du}{dx}$
11. $\frac{d}{dx} \log_a u = (\log_a e)(1/u) \frac{du}{dx}$	30. $\frac{d}{dx} \operatorname{csch} u = -\operatorname{csch} u \operatorname{ctnh} u \frac{du}{dx}$
12. $\frac{d}{dx} u^v = v u^{v-1} \frac{du}{dx} + u^v (\log_e u) \frac{dv}{dx}$	31. $\frac{d}{dx} \sinh^{-1} u = \frac{1}{\sqrt{u^2+1}} \frac{du}{dx}$
13. $\frac{d}{dx} \sin u = \cos u \frac{du}{dx}$	32. $\frac{d}{dx} \cosh^{-1} u = \frac{1}{\sqrt{u^2-1}} \frac{du}{dx}$
14. $\frac{d}{dx} \cos u = -\sin u \frac{du}{dx}$	33. $\frac{d}{dx} \tanh^{-1} u = \frac{1}{1-u^2} \frac{du}{dx}$
15. $\frac{d}{dx} \tan u = \sec^2 u \frac{du}{dx}$	34. $\frac{d}{dx} \operatorname{ctnh}^{-1} u = \frac{-1}{u^2-1} \frac{du}{dx}$
16. $\frac{d}{dx} \operatorname{ctn} u = -\operatorname{csc}^2 u \frac{du}{dx}$	35. $\frac{d}{dx} \operatorname{sech}^{-1} u = \frac{-1}{u\sqrt{1-u^2}} \frac{du}{dx}$
17. $\frac{d}{dx} \sec u = \sec u \tan u \frac{du}{dx}$	36. $\frac{d}{dx} \operatorname{csch}^{-1} u = \frac{-1}{u\sqrt{u^2+1}} \frac{du}{dx}$
18. $\frac{d}{dx} \csc u = -\csc u \operatorname{ctn} u \frac{du}{dx}$	
19. $\frac{d}{dx} \sin^{-1} u = \frac{1}{\sqrt{1-u^2}} \frac{du}{dx}, \quad (-\frac{1}{2}\pi \leq \sin^{-1} u \leq \frac{1}{2}\pi)$	

## Additional Relations with Derivatives

$$\frac{d}{dt} \int_a^t f(x) dx = f(t) \quad \frac{d}{dt} \int_t^a f(x) dx = -f(t)$$

$$\text{If } x = f(y), \text{ then } \frac{dy}{dx} = \frac{1}{\frac{dx}{dy}}$$

$$\text{If } y = f(u) \text{ and } u = g(x), \text{ then } \frac{dy}{dx} = \frac{dy}{du} \cdot \frac{du}{dx} \text{ (chain rule)}$$

$$\text{If } x = f(t) \text{ and } y = g(t), \text{ then } \frac{dy}{dx} = \frac{g'(t)}{f'(t)}, \text{ and } \frac{d^2y}{dx^2} = \frac{f'(t)g''(t) - g'(t)f''(t)}{[f'(t)]^3}$$

(Note: Exponent in denominator is 3.)

## A.8 Integrals

---

### Elementary Forms

1.  $\int a dx = ax$
2.  $\int a f(x) dx = a \int f(x) dx$
3.  $\int A(y) dx = \int \frac{A(y)}{y'} dy$ ; where  $y' = \frac{dy}{dx}$
4.  $\int (u + v) dx = \int u dx + \int v dx$ , where  $u$  and  $v$  are any functions of  $x$
5.  $\int u dv = uv - \int v du$
6.  $\int u \frac{dv}{dx} dx = uv - \int v \frac{du}{dx} dx$
7.  $\int x^n dx = \frac{x^{n+1}}{n+1}$ , except  $n = -1$
8.  $\int \frac{f'(x) dx}{f(x)} = \log f(x)$ ; [ $df(x) = f'(x) dx$ ]
9.  $\int \frac{dx}{x} = \log x$
10.  $\int \frac{f'(x) dx}{f^2(x)} = -\frac{1}{f(x)}$ ; [ $df(x) = f'(x) dx$ ]
11.  $\int e^x dx = e^x$

$$\begin{aligned}
12. \quad \int e^{ax} dx &= e^{ax} = a \\
13. \quad \int b^{ax} dx &= \frac{b^{ax}}{a \log b}; \quad (b > 0) \\
14. \quad \int \log x dx &= x \log x - x \\
15. \quad \int a^x \log a dx &= a^x; \quad (a > 0) \\
16. \quad \int \frac{dx}{a^2 + x^2} &= \frac{1}{a} \tan^{-1} \frac{x}{a} \\
17. \quad \int \frac{dx}{a^2 - x^2} &= \frac{1}{2a} \log \frac{a+x}{a-x}; \quad (a^2 > x^2) \\
18. \quad \int \frac{dx}{x^2 - a^2} &= \frac{1}{2a} \log \frac{x-a}{x+a}; \quad (x^2 > a^2) \\
19. \quad \int \frac{dx}{a^2 + x^2} &= \frac{1}{a} \tan^{-1} \frac{x}{a} \\
20. \quad \int \frac{dx}{x^2 - a^2} &= \log \left( x + \sqrt{x^2 - a^2} \right) \\
21. \quad \int \frac{dx}{x \sqrt{x^2 + a^2}} &= \frac{1}{a} \sec^{-1} \frac{x}{a} \\
22. \quad \int \frac{dx}{x \sqrt{a^2 - x^2}} &= -\frac{1}{a} \log \frac{a + \sqrt{a^2 - x^2}}{x}
\end{aligned}$$

## Forms Containing (a + bx)

For forms containing a + bx, but not listed in the table, the substitution u = (a + bx) = x may prove helpful.

$$23. \quad \int (a + bx)^n dx = \frac{(a + bx)^{n+1}}{(n+1)b}; \quad (n \neq -1)$$

$$24. \int x(a + bx)^n dx = \frac{1}{b^2(n+2)} (a + bx)^{n+2} - \frac{a}{b^2(n+1)} (a + bx)^{n+1}; \quad (n \neq -1; -2)$$

$$25. \int x^2(a + bx)^n dx = \frac{1}{b^3} \frac{(a + bx)^{n+3}}{n+3} - 2a \frac{(a + bx)^{n+2}}{n+2} + a^2 \frac{(a + bx)^{n+1}}{n+1} \\ - \frac{x^{m+1}(a + bx)^n}{m+n+1} + \frac{an}{m+n+1} \int x^m(a + bx)^{n-1} dx$$

$$26. \int x^m(a + bx)^n dx = \frac{1}{a(n+1)} \int x^{m+1}(a + bx)^{n+1} dx + (m+n+2) \int x^m(a + bx)^{n+1} dx \\ \text{or} \\ \frac{1}{b(m+n+1)} \int x^m(a + bx)^{n+1} dx - \frac{a}{b} \int x^{m-1}(a + bx)^n dx$$

$$27. \int \frac{dx}{a + bx} = \frac{1}{b} \log(a + bx)$$

$$28. \int \frac{dx}{(a + bx)^2} = -\frac{1}{b(a + bx)}$$

$$29. \int \frac{dx}{(a + bx)^3} = -\frac{1}{2b(a + bx)^2}$$

$$30. \int \frac{x dx}{a + bx} = \frac{1}{b^2} [a + bx - a \log(a + bx)]$$

$$\text{or} \\ \frac{x}{b} - \frac{a}{b^2} \log(a + bx)$$

$$31. \int \frac{x dx}{(a + bx)^2} = \frac{1}{b^2} \log(a + bx) + \frac{a}{a + bx}$$

$$32. \int \frac{x dx}{(a + bx)^n} = \frac{1}{b^2} \frac{1}{(n-2)(a + bx)^{n-2}} + \frac{a}{(n-1)(a + bx)^{n-1}}; \quad n \neq 1; 2$$

$$33. \int \frac{x^2 dx}{a + bx} = \frac{1}{b^3} \left[ \frac{1}{2}(a + bx)^2 - 2a(a + bx) + a^2 \log(a + bx) \right]$$

$$34. \int \frac{x^2 dx}{(a + bx)^2} = \frac{1}{b^3} \left[ a + bx - 2a \log(a + bx) - \frac{a^2}{a + bx} \right]$$

$$35. \int \frac{x^2 dx}{(a + bx)^3} = \frac{1}{b^3} \left[ \log(a + bx) + \frac{2a}{a + bx} - \frac{a^2}{2(a + bx)^2} \right]$$

$$\begin{aligned}
36. \quad \int \frac{x^2 dx}{(a+bx)^n} &= \frac{1}{b^3} \frac{i-1}{(n-i-3)(a+bx)^{n-i-3}} \\
&\quad + \frac{2a}{(n-i-2)(a+bx)^{n-i-2}} + i \frac{a^2}{(n-i-1)(a+bx)^{n-i-1}}; \quad n \neq 1; 2; 3 \\
37. \quad \int \frac{dx}{x(a+bx)} &= i \frac{1}{a} \log \frac{a+bx}{x} \\
38. \quad \int \frac{dx}{x(a+bx)^2} &= \frac{1}{a(a+bx)} + i \frac{1}{a^2} \log \frac{a+bx}{x} \quad \# \\
39. \quad \int \frac{dx}{x(a+bx)^3} &= \frac{1}{a^3} + \frac{1}{2} \frac{2a+bx}{a+bx} + \log \frac{x}{a+bx} \\
40. \quad \int \frac{dx}{x^2(a+bx)} &= i \frac{1}{ax} + \frac{b}{a^2} \log \frac{a+bx}{x} \\
41. \quad \int \frac{dx}{x^3(a+bx)} &= \frac{2bx-i}{2a^2x^2} + \frac{b^2}{a^3} \log \frac{x}{a+bx} \\
42. \quad \int \frac{dx}{x^2(a+bx)^2} &= i \frac{a+2bx}{a^2x(a+bx)} + \frac{2b}{a^3} \log \frac{a+bx}{x}
\end{aligned}$$

## A.9 The Fourier Transforms

For a piecewise continuous function  $F(x)$  over a finite interval  $0 \leq x \leq \frac{1}{4}$ , the *finite Fourier cosine transform* of  $F(x)$  is

$$f_c(n) = \int_0^{\frac{1}{4}} f(x) \cos nx \, dx \quad (n = 0; 1; 2; \dots) \quad (\text{A:1})$$

If  $x$  ranges over the interval  $0 \leq x \leq L$ , the substitution  $x^0 = \frac{1}{4}x = L$  allows the use of this definition also. The inverse transform is written

$$\overline{F}(x) = \frac{1}{4} f_c(0) + \sum_{n=1}^{\infty} f_c(n) \cos nx \quad (0 < x < \frac{1}{4}) \quad (\text{A:2})$$

where  $\overline{F}(x) = [F(x+0) + F(x-0)]/2$ . We observe that  $\overline{F}(x) = F(x)$  at points of continuity. The formula

$$\begin{aligned}
f_c^{(2)}(n) &= \int_0^{\frac{1}{4}} F''(x) \cos nx \, dx \\
&= -n^2 f_c(n) + F'(0) + (-1)^n F'(\frac{1}{4})
\end{aligned} \quad (\text{A:3})$$

makes the finite Fourier cosine transform useful in certain boundary value problems.

Analogously, the *finite Fourier sine transform* of  $F(x)$  is

$$f_s(n) = \int_0^{\frac{1}{4}} F(x) \sin nx \, dx \quad (n = 1; 2; 3; \dots) \quad (\text{A:4})$$

and

$$\bar{F}(x) = \frac{2}{\pi} \sum_{n=1}^{\infty} f_s(n) \sin nx \quad (0 < x < \pi/4) \quad (\text{A:5})$$

Corresponding to Eq. (A.6), we have

$$\begin{aligned} f_s^{(2)}(n) &= \int_0^{\pi/4} F''(x) \sin nx \, dx \\ &= (-1)^n f_s(n) - n F'(0) - n(-1)^n F(\pi/4) \end{aligned} \quad (\text{A:6})$$

## Fourier Transforms

If  $F(x)$  is defined for  $x \geq 0$  and is piecewise continuous over any finite interval, and if

$$\int_0^{\infty} F(x) \, dx$$

is absolutely convergent, then

$$f_c(\xi) = \int_0^{\infty} F(x) \cos(\xi x) \, dx \quad (\text{A:7})$$

is the *Fourier cosine transform* of  $F(x)$ . Furthermore,

$$\bar{F}(x) = \int_0^{\infty} f_c(\xi) \cos(\xi x) \, d\xi \quad (\text{A:8})$$

If  $\lim_{x \rightarrow \infty} d^n F/dx^n = 0$ , an important property of the Fourier cosine transform,

$$\begin{aligned} f_c^{(2r)}(\xi) &= \int_0^{\infty} \frac{d^{2r} F}{dx^{2r}} \cos(\xi x) \, dx \\ &= (-1)^r \sum_{n=0}^{\infty} \frac{(-1)^n a_{2r-2n}}{(2n)!} \xi^{2n} + (-1)^r \xi^{2r} f_c(\xi) \end{aligned} \quad (\text{A:9})$$

where  $\lim_{x \rightarrow 0} d^r F/dx^r = a_r$ , makes it useful in the solution of many problems.

Under the same conditions,

$$f_s(\xi) = \int_0^{\infty} F(x) \sin(\xi x) \, dx \quad (\text{A:10})$$

defines the *Fourier sine transform* of  $F(x)$ , and

$$\bar{F}(x) = \int_0^1 f_s(\xi) \sin(\xi x) d\xi \quad (A:11)$$

Corresponding to Eq. (A.9) we have

$$\begin{aligned} f_s^{(2r)}(\xi) &= \int_0^1 \frac{d^{2r} F}{dx^{2r}} \sin(\xi x) dx \\ &= i \int_0^1 \sum_{n=1}^{\infty} (i\xi)^{2n-1} a_{2n} + (i\xi)^{2r-1} f_s(\xi) \end{aligned} \quad (A:12)$$

Similarly, if  $F(x)$  is defined for  $-1 < x < 1$ , and if  $\int_{-1}^1 F(x) dx$  is absolutely convergent, then

$$f(\xi) = \int_{-1}^1 F(x) e^{i\xi x} dx \quad (A:13)$$

is the *Fourier transform* of  $F(x)$ , and

$$\bar{F}(x) = \int_{-1}^1 f(\xi) e^{i\xi x} d\xi \quad (A:14)$$

Also, if

$$\lim_{|x| \rightarrow 1} \left| \frac{d^n F}{dx^n} \right| = 0 \quad (n = 1, 2, \dots, r-1)$$

then

$$f^{(r)}(\xi) = \int_{-1}^1 F^{(r)}(x) e^{i\xi x} dx = (i\xi)^r f(\xi) \quad (A:15)$$

## Finite Sine Transforms

$f_s(n)$	$F(x)$
1. $f_s(n) = \int_0^\pi F(x) \sin nx dx \quad (n = 1, 2, \dots)$	$F(x)$
2. $(-1)^{n+1} f_s(n)$	$F(\pi - x)$
3. $\frac{1}{n}$	$\frac{\pi - x}{\pi}$
4. $\frac{(-1)^{n+1}}{n}$	$\frac{x}{\pi}$
5. $\frac{1 - (-1)^n}{n}$	1

$f_s(n)$	$F(x)$
6. $\frac{2}{n^2} \sin \frac{n\pi}{2}$	$\begin{cases} x & \text{when } 0 < x < \pi/2 \\ \pi - x & \text{when } \pi/2 < x < \pi \end{cases}$
7. $\frac{(-1)^{n+1}}{n^3}$	$\frac{x(\pi^2 - x^2)}{6\pi}$
8. $\frac{1 - (-1)^n}{n^3}$	$\frac{x(\pi - x)}{2}$
9. $\frac{\pi^2(-1)^{n-1}}{n} - \frac{2[1 - (-1)^n]}{n^3}$	$x^2$
10. $\pi(-1)^n \left( \frac{6}{n^3} - \frac{\pi^2}{n} \right)$	$x^3$
11. $\frac{n}{n^2 + c^2} [1 - (-1)^n e^{c\pi}]$	$e^{cx}$
12. $\frac{n}{n^2 + c^2}$	$\frac{\sinh c(\pi - x)}{\sinh c\pi}$
13. $\frac{n}{n^2 - k^2} \quad (k \neq 0, 1, 2, \dots)$	$\frac{\sinh k(\pi - x)}{\sin k\pi}$
14. $\begin{cases} \frac{\pi}{2} & \text{when } n = m \\ 0 & \text{when } n \neq m \end{cases} \quad (m = 1, 2, \dots)$	$\sin mx$
15. $\frac{n}{n^2 - k^2} [1 - (-1)^n \cos k\pi] \quad (k \neq 1, 2, \dots)$	$\cos kx$
16. $\begin{cases} \frac{n}{n^2 - m^2} [1 - (-1)^{n+m}] & \text{when } n \neq m = 1, 2, \dots \\ 0 & \text{when } n = m \end{cases}$	$\cos mx$
17. $\frac{n}{(n^2 - k^2)^2} \quad (k \neq 0, 1, 2, \dots)$	$\frac{\pi \sin kx}{2k \sin^2 k\pi} - \frac{x \cos k(\pi - x)}{2k \sin k\pi}$
18. $\frac{b^n}{n} \quad ( b  \leq 1)$	$\frac{2}{\pi} \arctan \frac{b \sin x}{1 - b \cos x}$
19. $\frac{1 - (-1)^n}{n} b^n \quad ( b  \leq 1)$	$\frac{2}{\pi} \arctan \frac{2b \sin x}{1 - b^2}$

## Finite Cosine Transforms

$f_c(n)$	$F(x)$
1. $f_c(n) = \int_0^\pi F(x) \cos nx \, dx \quad (n = 0, 1, 2, \dots)$	$F(x)$
2. $(-1)^n f_c(n)$	$F(\pi - x)$
3. 0 when $n = 1, 2, \dots$ ; $f_c(0) = \pi$	1
4. $\frac{2}{n} \sin \frac{n\pi}{2}$ ; $f_c(0) = 0$	$\begin{cases} 1 & \text{when } 0 < x < \pi/2 \\ -1 & \text{when } \pi/2 < x < \pi \end{cases}$
5. $-\frac{1 - (-1)^n}{n^2}$ ; $f_c(0) = \frac{\pi^2}{2}$	$x$
6. $\frac{(-1)^n}{n^2}$ ; $f_c(0) = \frac{\pi^2}{6}$	$\frac{x^2}{2\pi}$
7. $\frac{1}{n^2}$ ; $f_c(0) = 0$	$\frac{(\pi - x)^2}{2\pi} - \frac{\pi}{6}$
8. $3\pi^2 \frac{(-1)^n}{n^2} - 6 \frac{1 - (-1)^n}{n^4}$ ; $f_c(0) = \frac{\pi^4}{4}$	$x^3$
9. $\frac{(-1)^n e^c \pi - 1}{n^2 + c^2}$	$\frac{1}{c} e^{cx}$

$f_c(n)$	$F(x)$
10. $\frac{1}{n^2 + c^2}$	$\frac{\cosh c(\pi - x)}{c \sinh c\pi}$
11. $\frac{k}{n^2 - k^2} [(-1)^n \cos \pi k - 1] \quad (k \neq 0, 1, 2, \dots)$	$\sin kx$
12. $\frac{(-1)^{n+m} - 1}{n^2 - m^2}$ ; $f_c(m) = 0 \quad (m = 1, 2, \dots)$	$\frac{1}{m} \sin mx$
13. $\frac{1}{n^2 - k^2} \quad (k \neq 0, 1, 2, \dots)$	$-\frac{\cos k(\pi - x)}{k \sin k\pi}$
14. 0 when $n = 1, 2, \dots$ ; $f_c(m) = \frac{\pi}{2} \quad (m = 1, 2, \dots)$	$\cos mx$

## Fourier Sine Transforms

$F(x)$	$f_s(\alpha)$
1. $\begin{cases} 1 & (0 < x < a) \\ 0 & (x > a) \end{cases}$	$\sqrt{\frac{2}{\pi}} \left[ \frac{1 - \cos \alpha}{\alpha} \right]$
2. $x^{p-1} \quad (0 < p < 1)$	$\sqrt{\frac{2}{\pi}} \frac{\Gamma(p)}{\alpha^p} \sin \frac{p\pi}{2}$
3. $\begin{cases} \sin x & (0 < x < a) \\ 0 & (x > a) \end{cases}$	$\frac{1}{\sqrt{2\pi}} \left[ \frac{\sin[a(1-\alpha)]}{1-\alpha} - \frac{\sin[a(1+\alpha)]}{1+\alpha} \right]$
4. $e^{-x}$	$\sqrt{\frac{2}{\pi}} \left[ \frac{\alpha}{1+\alpha^2} \right]$
5. $xe^{-x^2/2}$	$\alpha e^{-\alpha^2/2}$
6. $\cos \frac{x^2}{2}$	$\sqrt{2} \left[ \sin \frac{\alpha^2}{2} C\left(\frac{\alpha^2}{2}\right) - \cos \frac{\alpha^2}{2} S\left(\frac{\alpha^2}{2}\right) \right]^*$
7. $\sin \frac{x^2}{2}$	$\sqrt{2} \left[ \cos \frac{\alpha^2}{2} C\left(\frac{\alpha^2}{2}\right) + \sin \frac{\alpha^2}{2} S\left(\frac{\alpha^2}{2}\right) \right]^*$

\*  $C(y)$  and  $S(y)$  are the Fresnel integrals

$$C(y) = \frac{1}{\sqrt{2\pi}} \int_0^y \frac{1}{\sqrt{t}} \cos t \, dt$$

$$S(y) = \frac{1}{\sqrt{2\pi}} \int_0^y \frac{1}{\sqrt{t}} \sin t \, dt$$

## Fourier Cosine Transforms

$F(x)$	$f_c(\alpha)$
1. $\begin{cases} 1 & (0 < x < a) \\ 0 & (x > a) \end{cases}$	$\sqrt{\frac{2}{\pi}} \frac{\sin a \alpha}{\alpha}$
2. $x^{p-1} \quad (0 < p < 1)$	$\sqrt{\frac{2}{\pi}} \frac{\Gamma(p)}{\alpha^p} \cos \frac{p\pi}{2}$
3. $\begin{cases} \cos x & (0 < x < a) \\ 0 & (x > a) \end{cases}$	$\frac{1}{\sqrt{2\pi}} \left[ \frac{\sin[a(1-\alpha)]}{1-\alpha} + \frac{\sin[a(1+\alpha)]}{1+\alpha} \right]$

$F(x)$	$f_c(\alpha)$
4. $e^{-x}$	$\sqrt{\frac{2}{\pi}} \left( \frac{1}{1+\alpha^2} \right)$
5. $e^{-x^2/2}$	$e^{-\alpha^2/2}$
6. $\cos \frac{x^2}{2}$	$\cos \left( \frac{\alpha^2}{2} - \frac{\pi}{4} \right)$
7. $\sin \frac{x^2}{2}$	$\cos \left( \frac{\alpha^2}{2} - \frac{\pi}{4} \right)$

# Fourier Transforms

$F(x)$	$f(\alpha)$
1. $\frac{\sin ax}{x}$	$\begin{cases} \sqrt{\frac{\pi}{2}} &  \alpha  < a \\ 0 &  \alpha  > a \end{cases}$
2. $\begin{cases} e^{iwx} & (p < x < q) \\ 0 & (x < p, x > q) \end{cases}$	$\frac{i}{\sqrt{2\pi}} \frac{e^{ip(w+\alpha)} - e^{iq(w+\alpha)}}{(w+\alpha)}$
3. $\begin{cases} e^{-cx+iwx} & (x > 0) \\ 0 & (x < 0) \end{cases} \quad (c > 0)$	$\frac{i}{\sqrt{2\pi}(w+\alpha+ic)}$
4. $e^{-px^2} \quad R(p) > 0$	$\frac{1}{\sqrt{2p}} e^{-\alpha^2/4p}$
5. $\cos px^2$	$\frac{1}{\sqrt{2p}} \cos \left[ \frac{\alpha^2}{4p} - \frac{\pi}{4} \right]$
6. $\sin px^2$	$\frac{1}{\sqrt{2p}} \cos \left[ \frac{\alpha^2}{4p} + \frac{\pi}{4} \right]$
7. $ x ^{-p} \quad (0 < p < 1)$	$\sqrt{\frac{2}{\pi}} \frac{\Gamma(1-p) \sin \frac{p\pi}{2}}{ \alpha ^{(1-p)}}$
8. $\frac{e^{-a x }}{\sqrt{ x }}$	$\frac{\sqrt{\sqrt{(a^2 + \alpha^2)} + a}}{\sqrt{a^2 + \alpha^2}}$
9. $\frac{\cosh ax}{\cosh \pi x} \quad (-\pi < a < \pi)$	$\sqrt{\frac{2}{\pi}} \frac{\cos \frac{a}{2} \cosh \frac{\alpha}{2}}{\cosh \alpha + \cos a}$
10. $\frac{\sinh ax}{\sinh \pi x} \quad (-\pi < a < \pi)$	$\frac{1}{\sqrt{2\pi}} \frac{\sin a}{\cosh \alpha + \cos a}$
11. $\begin{cases} \frac{1}{\sqrt{a^2 - x^2}} & ( x  < a) \\ 0 & ( x  > a) \end{cases}$	$\sqrt{\frac{\pi}{2}} J_0(a\alpha)$
12. $\frac{\sin[b\sqrt{a^2 + x^2}]}{\sqrt{a^2 + x^2}}$	$\begin{cases} 0 & ( \alpha  > b) \\ \sqrt{\frac{\pi}{2}} J_0(a\sqrt{b^2 - \alpha^2}) & ( \alpha  < b) \end{cases}$

$F(x)$	$f(\alpha)$
13. $\begin{cases} P_n(x) & ( x  < 1) \\ 0 & ( x  > 1) \end{cases}$	$\frac{i^n}{\sqrt{\alpha}} j_{n+1/2}(\alpha)$
14. $\begin{cases} \frac{\cos[b \sqrt{a^2 - x^2}]}{\sqrt{a^2 - x^2}} & ( x  < a) \\ 0 & ( x  > a) \end{cases}$	$\sqrt{\frac{\pi}{2}} J_0(a \sqrt{a^2 + b^2})$
15. $\begin{cases} \frac{\cosh[b \sqrt{a^2 - x^2}]}{\sqrt{a^2 - x^2}} & ( x  < a) \\ 0 & ( x  > a) \end{cases}$	$\sqrt{\frac{\pi}{2}} J_0(a \sqrt{a^2 - b^2})$

The following functions appear among the entries of the tables on transforms.

Function	Definition	Name
$\text{Ei}(x)$	$\int_{-\infty}^x \frac{e^v}{v} dv$ ; or sometimes defined as $-\text{Ei}(-x) = \int_x^{\infty} \frac{e^{-v}}{v} dv$	Exponential integral function
$\text{Si}(x)$	$\int_0^x \frac{\sin v}{v} dv$	Sine integral function
$\text{Ci}(x)$	$\int_{\infty}^x \frac{\cos v}{v} dv$ ; or sometimes defined as negative of this integral	Cosine integral function
$\text{erf}(x)$	$\frac{2}{\sqrt{\pi}} \int_0^x e^{-v^2} dv$	Error function
$\text{erfc}(x)$	$1 - \text{erf}(x) = \frac{2}{\sqrt{\pi}} \int_x^{\infty} e^{-v^2} dv$	Complementary function to error function
$L_n(x)$	$\frac{e^x}{n!} \frac{d^n}{dx^n} (x^n e^{-x})$ , $n = 0, 1, \dots$	Laguerre polynomial of degree $n$

## A.10 Bessel Functions

---

### Bessel Functions of the First Kind, $J_n(x)$ (Also Called Simply *Bessel Functions*) (Fig. A.13)

Domain:  $[x > 0]$

Recurrence relation:

$$J_{n+1}(x) = \frac{2n}{x} J_n(x) - J_{n-1}(x); \quad n = 0; 1; 2; \dots$$

Symmetry:  $J_{-n}(x) = (-1)^n J_n(x)$

0.  $J_0(20x)$
1.  $J_1(20x)$
2.  $J_2(20x)$
3.  $J_3(20x)$
4.  $J_4(20x)$
5.  $J_5(20x)$

**Figure A.13** Bessel functions of the first kind.

### Bessel Functions of the Second Kind, $Y_n(x)$ (Also Called *Neumann Functions* or *Weber Functions*) (Fig. A.14)

Domain:  $[x > 0]$

Recurrence relation:

$$Y_{n+1}(x) = \frac{2n}{x} Y_n(x) - Y_{n-1}(x); \quad n = 0; 1; 2; \dots$$

$$\text{Symmetry: } Y_{i-n}(x) = (-1)^n Y_n(x)$$

0.  $Y_0(20x)$
1.  $Y_1(20x)$
2.  $Y_2(20x)$
3.  $Y_3(20x)$
4.  $Y_4(20x)$
5.  $Y_5(20x)$

**Figure A.14** Bessel functions of the second kind.

## A.11 Legendre Functions

### Associated Legendre Functions of the First Kind, $P_n^m(x)$ (Fig. A.15)

Domain:  $[-1 < x < 1]$

Recurrence relations:

$$P_{n+1}^m(x) = \frac{(2n+1)xP_n^m - (n+m)P_{n-1}^m(x)}{n-m+1}; \quad n = 1; 2; 3; \dots$$

$$P_n^{m+1}(x) = (x^2 - 1)^{1/2} [(n-m)P_n^m(x) - (n+m)P_{n-1}^m(x)]; \quad m = 0; 1; 2; \dots$$

with

$$P_0^0 = 1 \quad P_1^0 = x$$

**Figure A.15** Bessel functions of the second kind.

Special case:  $P_n^0 =$  Legendre polynomials

1-0.  $P_0^0(x)$

1-1.  $P_1^0(x)$

1-2.  $P_2^0(x)$

1-3.  $P_3^0(x)$

1-4.  $P_4^0(x)$

2-1.  $0.25 P_1^1(x)$

2-2.  $0.25 P_2^1(x)$

2-3.  $0.25 P_3^1(x)$

2-4.  $0.25 P_4^1(x)$

3-2.  $0.10 P_2^2(x)$

3-3.  $0.10 P_3^2(x)$

3-4.  $0.10 P_4^2(x)$

4-3.  $0.025 P_3^3(x)$

4-4.  $0.025 P_4^3(x)$

## A.12 Table of Differential Equations

	Equation	Solution
1.	$y' = \frac{dy}{dx} = f(x)$	$y = \int f(x) dx + c$
2.	$y' + p(x)y = q(x)$	$y = \exp[-\int p(x) dx] \{c + \int \exp[\int p(x) dx] q(x) dx\}$
3.	$y' + p(x)y = q(x)y^\alpha$ $\alpha \neq 0, \alpha \neq 1$	Set $z = y^{1-\alpha} \rightarrow z' + (1-\alpha)p(x)z = (1-\alpha)q(x)$ and use 2
4.	$y' = f(x)g(y)$	Integrate $\frac{dy}{g(y)} = f(x) dx$ (separable)
5.	$\frac{dy}{dx} = f(x/y)$	Set $y = xu \rightarrow u + x \frac{du}{dx} = f(u)$ $\int \frac{1}{f(u) - u} du = \ln x  + c$
6.	$y' = f\left(\frac{a_1x + b_1y + c_1}{a_2x + b_2y + c_2}\right)$	Set $x = X + \alpha, y = Y + \beta$ Choose $\begin{cases} a_1\alpha + b_1\beta = -c_1 \\ a_2\alpha + b_2\beta = -c_2 \end{cases} \rightarrow Y' = f\left(\frac{a_1X + b_1Y}{a_2X + b_2Y}\right)$ If $a_1b_2 - a_2b_1 \neq 0$ , set $Y = Xu \rightarrow$ separable form $u + Xu' = f\left(\frac{a_1 + b_1u}{a_2 + b_2u}\right)$ If $a_1b_2 - a_2b_1 = 0$ , set $u = a_1x + b_1y \rightarrow$ $\frac{du}{dx} = a_1 + b_1f\left(\frac{u + c_1}{ku + c_2}\right)$ since $a_2x + b_2y = k(a_1x + b_1y)$
7.	$y'' + a^2y = 0$	$y = c_1 \cos ax + c_2 \sin ax$
8.	$y'' - a^2y = 0$	$y = c_1 e^{ax} + c_2 e^{-ax}$
9.	$y'' + ay' + by = 0$	Set $y = e^{-(a/2)x} u \rightarrow u'' + \left(b - \frac{a^2}{4}\right)u = 0$
10.	$y'' + a(x)y' + b(x)y = 0$	Set $y = e^{-(1/2)\int a(x) dx} \rightarrow u'' + \left[b(x) - \frac{a^2}{4} - \frac{a'}{2}\right]u = 0$
11.	$x^2y'' + xy' + (x^2 - a^2)y = 0$ $a \geq 0$ (Bessel)	i. If $a$ is not an integer $y = c_1 J_a(x) + c_2 J_{-a}(x)$ (Bessel functions of first kind) ii. If $a$ is an integer (say, $n$ ) $y = c_1 J_n(x) + c_2 Y_n(x)$ ( $Y_n$ is Bessel function of second kind)
12.	$(1 - x^2)y'' - 2xy' + a(a + 1)y = 0$ , $a$ is real (Legendre)	$y(x) = c_1 p_a(x) + c_2 q_a(x)$ (Legendre functions)
13.	$y' + ay^2 = bx^n$ (integrable Riccati) $a, b, n$ real	Set $u' = ayu \rightarrow u'' - abx^n u = 0$ and use 14
